PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Office
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-03
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1975.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *World Medical Periodicals*, 3rd Edition, are used.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

5197 EFFECT OF TRASYLOL® ON PANETH CELLS OF THE MOUSE. *(E.)* Ahonen, A.; Penttila, A. (Dep. Anat., Univ. Helsinki, Finland). *Experientia* 31(5):577-578, 1975.

The morphological effects of Trasylol^{R}, a trypsin and proteinase inhibitor, were studied in intestinal Paneth cells. Mice were fasted for 1 day, but received water *ad libitum*. Ten mice received an i.p. dose of 40,000 IU/kg Trasylol and seven controls received an equal dose of 0.9% saline solution. The animals were decapitated 1 hr later. Tissue samples from the mid-duodenum and mid-jejunum were formalin-fixed, paraffin-embedded, sectioned (7 μm) and stained with Best's carmine. The number of cytoplasmic coarse granules of Paneth cells was counted under a light microscope (400 cells from the experimental animals and 600 from the controls were studied). The number of identifiable Paneth cells in an intestinal crypt was higher in Trasylol-treated mice than in controls 1 hr after injection; the mean diameter of Paneth cells was also higher. There was a highly significant increase in the mean number of secretory granules/cell; from 12.1 to 17.1 in the duodenum, and from 8.3 to 19.7 in the jejunum. The inhibitory effect of Trasylol on Paneth cells is similar to the agents' effect on pancreatic acinar cells. It is suggested that the Paneth cells are morphologically, functionally and embryologically related to pancreatic acinar cells, and that the underlying mechanism for the increase of counts of secretory granules may result from delayed extrusion of the granules from the cell cytoplasm into the intestinal lumen.

5198 IDENTIFICATION OF THE INTESTINAL CELL STORING GASTRIC INHIBITORY PEPTIDE. *(E.)* Buffa, R.; Polak, J. M.; Pearse, A. G. E.; Solcia, E.; Grimelius, L.; Capella, C. (Inst. Pathol. Anat., Univ. Pavia, Italy). *Histochemistry* 43(3):249-255, 1975.

A recently-described intestinal endocrine cell was studied to determine its possible role in the production of gastric inhibitory peptide. Small intestinal mucosa samples from man, pig and dog were subjected to sequential or correlative silver impregnation techniques, applied to immunocytochemical preparations and at the ultrastructural level. The cell reacting with antigastric inhibitory peptide sera was identified as the ultrastructurally classified K cell. It was recognized by strong reactivity with the Sevier-Munger staining procedure and was chosen as the peptide-producing cell, provided that the equally strong-reacting enterochromaffin cell was excluded by virtue of its argentaffinity with the Masson technique. It is proposed that the term "gastric inhibitory peptide cell" be used to designate the K cell.

5199 INFLUENCE OF GLUCOCORTICOIDS ON SOME MORPHOLOGICAL AND BIOCHEMICAL ASPECTS OF RAT SMALL INTESTINAL MUCOSA. *(E.)* Lafont, J.; Pilon, R. (Lab. Biochim. Proteins, Univ. Sci. Tech. Languedoc, Montpellier, France). *Biochim. Biophys. Acta* 392(2):288-298, 1975.

The effect of cortisone on the rat small intestine during the post-weaning period was studied using male and female SPF rats (28-30 days old), injected with hydrocortisone (0.02, 0.1, 0.5, or 5 mg/100 g daily) i.p. or s.c. for 3 or 8 days. In another experiment, rats were injected daily with 25 μg/100 g of ACTH for 4 days. (^{3}H)thymidine was injected i.p. 0.5-12 or 24 hr before killing and cell migrations and the protein and alkaline phosphatase contents of the small intestinal mucosa were measured after sacrifice. Hydrocortisone at 5 mg/100 g for 3 days resulted in a 30% reduction in body weight and a 28% reduction in the protein content of the intestinal mucosa compared with control values. No differences were found following administration of 0.5 mg/100 g hydrocortisone for 3 days or after the administration of 0.02 or 0.1 mg hydrocortisone/100 g for 8 days. Similarly, there were no changes in body weight or intestinal mucosal protein following ACTH administration. Hydrocortisone (5 mg/100 g) caused a marked reduction in the activities of maltase and alkaline phosphatase, while ACTH elicited a specific rise in the activities of these enzymes. The opposing effects of glucocorticoid treatment and corticotrophic treatment do not appear to depend on enzyme activation, membrane stabilization, or on modifications of proliferative parameters in the intestinal epithelium. Rather, they appear to derive from the same origin, e.g., the action of glycocorticoids on the enterocyte differentiation.

5200 CHANGES IN INTESTINAL CELL KINETICS IN THE SMALL INTESTINE OF LACTATING MICE. *(E.)* Harding, J. D.; Cairnie, A. B. (Dep. Biol., Queen's Univ., Kingston, Canada). *Cell Tissue Kinet.* 8(2): 135-144, 1975.

Alterations in the proliferative characteristics of the epithelium of the mouse small intestine during lactation were studied. Virgin, pregnant (sixteenth day), lactating (fifteenth day) with 8 pups, and 15-day parous but nonlactating Swiss Webster mice were injected i.p. with ^{3}H-thymidine and, in some cases, with ^{14}C-thymidine prior to sacrifice. The number of crypts and villi in the jejunum and ileum were determined, as was the percentage of labeled mitoses. As compared with the virgin mice, the small intestine in the lactating mice was increased in size and weight. The turnover time of nonproliferating, postmitotic cells was similar in the virgin and lactating mice, as was the number of crypts. However, there was a small increase in crypt cell number in the pregnant mice and a larger increase in the lactating females (130%

increase) as compared with the virgin females. The number of crypt cells incorporating tritiated thymidine was also increased during lactation and there was evidence that the intestinal proliferating cells were cycling slightly faster in the lactating mice. The number of proliferating cells/crypt in the lactating mice was increased by 63% over the number seen in the virgin animals. Food consumption increased slightly over control levels during pregnancy and increased considerably during lactation. Lactating females in which food consumption was restricted to control levels showed increases in intestinal wet weight and intestinal crypt cell number, but the increases were smaller than those seen in lactating females fed *ad libitum*. The results suggest that food consumption, the hormonal state of the mother, and the metabolic demands of lactation all contribute to the intestinal hyperplasia seen in the lactating mouse.

5201 NEURAL STIMULATION OF MITOTIC ACTIVITY IN THE CRYPTS OF LIEBERKUHN IN RAT JEJUNUM.

(E.) Tutton, P. J. M. (Dep. Anat., Monash Univ., Victoria, Australia). *Cell Tissue Kinet.* 8(3):259-266, 1975.

The influence of nerve stimulation and sham-stimulation on the mitotic rate of the epithelial cells lining the crypts of Lieberkühn in the jejunum of anesthetized male Sprague-Dawley rats was studied. Administration of the anesthetic (pentobarbitone sodium) and opening of the abdominal cavity were without significant effect on the crypt cell mitotic rate, which was measured 1-4 hr following the i.p. administration of cholchicine (0.1 mg/kg). Neural stimulation involved the passage of electrical current through the mesenteric nerves of an externalized loop of jejunum, while sham-stimulation involved placing the electrodes on the neurovascular bundle of the loop without passing current through them. These procedures were carried out in normal rats and in rats which had been chemically sympathectomized 3 days previously by the injection of 6-hydroxydopamine at a dose of 100 mg/kg. Externalization of a jejunal loop and application of sham-stimuli to its mesenteric nerves resulted in a significant decrease in the crypt cell mitotic rate in that loop, while the application of electrical stimuli resulted in a significant increase in the mitotic rate in the crypt cells of that segment. Similar acceleration of crypt cell proliferation by electrical stimuli applied to the mesenteric nerves was also seen in the chemically sympathectomized rats. Although the nature of the nonadrenergic nerves mediating this response is unknown at present, acetylcholinergic, serotoninergic, and/or histaminergic nerves may be involved.

5202 A REGION OF MITOCHONDRIAL DIVISION IN THE EPITHELIUM OF THE SMALL INTESTINE OF THE RAT.

(E.) Jeynes, B. J.; Altmann, G. G. (Dep. Anat., Univ. West. Ontario, London, Canada). *Anat. Rec.* 182(3):289-296, 1975.

Ultrastructural details and mitochondrial concentrations in various regions of the small intestines of adult male Wistar rats were studied by electron microscopy. Intestinal samples were removed immediately after sacrifice at the levels of the duodenum, the jejunum and the proximal, mid, and distal ileum. Similar segments were taken from animals perfused with 3% glutaraldehyde, from animals given methotrexate (5 mg s.c. followed by 1-3 days dietary intake of 5 mg) and from animals in which the jejunum had been surgically isolated 3 weeks previously. In the control animals, the average mitochondrial number/cell section was 21 in the lower third of the crypts; it then gradually increased in the mid and upper thirds of the crypts, reaching about 42 at the villus base and remaining constant along the epithelium of the villi. The known forms of dividing mitochondria were identified in the mid and upper third of the crypts; these figures were rarely observed in the lower crypt and never seen on the villus. Crypt cells were continually produced in the lower crypt. These cells migrated to the villi while differentiating into nonproliferative absorptive cells. After methotrexate-induced mitotic inhibition, this migration continued and mitochondrial division persisted, although cell morphology was greatly changed by the third day of treatment. In segments of the jejunum isolated surgically from the functional intestine for 3 weeks, mitosis and cell migration continued, but no evidence of mitochondrial duplication was found. The results suggest that each mitochondrion probably undergoes a division as the crypt cells migrate from the mid-crypts to the villus. As a result, the villus epithelial cells contain double numbers of mitochondria. The mitochondrial division does not appear to be directly related to mitosis and is apparently elicited by a stimulus present only in the functional intestine.

5203 EARLY LYMPHOEPITHELIAL RELATIONSHIPS IN HUMAN APPENDIX: A COMBINED LIGHT- AND ELECTRON-MICROSCOPIC STUDY.

(E.) Bockman, D. E.; Cooper, M. D. (Med. Coll. Ohio, Toledo). *Gastroenterology* 68(5):1160-1168, 1975.

The relationship between the developing lymphoid follicles and epithelium in the appendix of human fetuses and children was examined by light and electron microscopy. Appendices were obtained from nine apparently normal fetuses, one stillborn child, and five children ranging in age from 5 months to 8 yr. Follicular accumulations of lymphocytes were observed first in the mesenchyme of an 11.5-cm fetus immediately beneath the epithelium, which contained a predominance of goblet cells on the surface and in the crypts. Larger accumulations of lymphoid cells in older fetuses (15 cm and larger) were intimately related to the surface epithelium but not to the epithelium of the crypts. At the point of invasion of the lymphoid cells into the surface epithelium, the goblet cell population diminished and epithelial cells displaying a morphologically distinct form of differentiation were observed. They were characterized by the presence of irregular microvilli or microfolds and numerous apical micropinocytotic vesicles. This follicle-associated epithelium (FAE) appeared ultrastructurally identical with the epithelium in the chicken bursa of Fabricius, the murine Peyer's patch and the rabbit appendix, which has been shown to be capable of transporting ferritin and India ink tracer from the lumen to underlying tissue. The FAE also appeared identical to the specialized epithelial cells of the adult human Peyer's patches. No FAE was observed in the youngest fetuses (11.5 cm and less), but was maintained throughout the later neonatal period into childhood. It is suggested that the FAE may provide a channel through which antigens may stimulate clonal proliferation and seeding of B-lymphocytes throughout the lamina propria of the internal mucous surfaces.

5204 CYTOCHEMICAL LOCALIZATION OF ADENYL CYCLASE IN THE RAT COLONIC MUCOSA. *(E.)* Corriveau, M.; Rojo-Ortega, J. M. (Clin. Res. Inst. Montreal, Canada). *Virchows Arch. Zellpathol.* 18(2):129-134, 1975.

The cellular distribution of adenyl cyclase was studied at the ultrastructural level in the rat colonic mucosa. Segments of the ascending and descending colonic mucosa of adult male Sprague-Dawley rats were incubated in medium containing 4 mM lead nitrate. The lead ions caused precipitation of the pyrophosphate formed by adenyl cyclase reacting with adenylylimidodiphosphate in the incubation medium. By this method, adenyl cyclase activity was localized in the brush border of the epithelial cells of the surface epithelium of the ascending colon. In the descending colon, coarse precipitates were located mainly in the basement membrane, in the junctional areas between epithelial cells, and on the brush border of all epithelial cells. Hydrolysis of the substrate was accelerated by the addition of 10 mM sodium fluoride to the incubation medium. The results suggest that the adenyl cyclase present in the basement membrane, plasma membrane, and in the brush borders may play a role in the regulation of intestinal transport. They also suggest that the colonic membrane may play a more crucial role in intestinal regulation than that of a simple filtration barrier.

5205 SMALL INTESTINAL MUCOSAL INJURY IN THE EXPERIMENTAL BLIND LOOP SYNDROME: LIGHT- AND ELECTRON-MICROSCOPIC AND HISTOCHEMICAL STUDIES. *(E.)* Toskes, P. P.; Giannella, R. A.; Jervis, H. R.; Rout, W. R.; Takeuchi, A. (Dep. Hematol., Walter Reed Army Inst. Res., Washington, D.C.). *Gastroenterology* 68(5):1193-1203, 1974.

The morphological integrity of the small intestine was investigated by light and electron microscopic and histochemical methods in male Walter Reed Carworth Farms rats with the experimental blind loop syndrome. Three groups of animals were studied: normal control animals and animals with either self-filling (SF) or self-emptying (SE) jejunal blind loops constructed surgically 10 cm distal to the ligament of Treitz. The blind loop segment and the jejunal segments proximal and distal to the blind loop were examined. Vitamin B_{12} malabsorption and bacterial overgrowth occurred only in the animals with SF blind loops, the most striking findings occurring in the blind loop itself with similar but less marked changes in the jejunum distal but not proximal to the blind loop segment. Hypertrophy of both crypts and villi was evident with focal abnormalities of the villus architecture, approximately 10-20% of the columnar cells in the upper half of the villi being swollen and vesiculated. By electron microscopy, the microvilli demonstrated a variety of degenerative changes and the glycocalyx and terminal web were disrupted. In addition, the mitochondrial and endoplasmic reticulum (ER), both smooth and rough, were swollen and concentric whorls of parallel membranes and long, curvilinear rough ER were present in the cytoplasm. Histochemically, there was loss of enzymatic activity in the epithelial brush border, mitochondria, and ER. Inasmuch as bacterial invasion of the jejunal mucosa was not seen, the etiology of these changes is unknown but may involve bacterial "toxins" or products of bacterial metabolism. These morphological observations demonstrate that both brush border and intracellular injury occur in the jejunal epithelial cells of rats with the experimental blind loop syndrome.

5206 FLUORESCENCE HISTOCHEMISTRY OF THE GASTRIN CELL IN FETAL AND ADULT MAN. *(E.)* Larsson, L. I.; Hakanson, R.; Sjoberg, N. O.; Sundler, F. (Dep. Histol., Univ. Lund, Sweden). *Gastroenterology* 68(5):1152-1159, 1975.

The histochemical properties of cells within the antral and duodenal mucosa and pancreatic islets which show gastrin immunoreactivity were compared in material from fetal and adult humans. Material from the adult and fetal antropyloric mucosa and proximal duodenal mucosa and adult pancreas were exposed to formaldehyde gas-ozone treatment or formaldehyde gas-hydrochloric acid treatment and examined using immunohistochemical techniques and fluorescence microscopy. Immunoreactive gastrin cells were demonstrated in both the adult and fetal duodenal mucosa and in the adult antropyloric mucosa; only a few scattered gastrin cells were detected in the antral mucosa of fetuses of 19-20 weeks gestation, but these cells were present in large numbers in the antral mucosa of two stillborn infants. No gastrin immunoreactivity was seen in the pancreatic islets. The antral and duodenal gastrin cells, as well as the pancreatic A_2-cells, displayed strong formaldehyde-ozone- and formaldehyde-HCl-induced fluorescence, whereas the pancreatic A_1-cells (previously claimed to store gastrin) were nonfluorescent. The fluorescence histochemical properties of the fetal gastrin cells did not differ from those of the adult material. The results suggest a relationship between immunoreactive gastrin and a postulated peptide having NH_2-terminal tryptophan.

5207 DIRECT EFFECTS OF ENDOTOXIN ON CANINE GASTRIC MUCOSAL PERMEABILITY AND MORPHOLOGY. *(E.)* Cheung, L. Y.; Stephenson, L. W.; Moody, F. G.; Torma, M. J.; Zalewsky, C. (Univ. Utah Med. Cent., Salt Lake City). *J. Surg. Res.* 18(4):417-425, 1975.

The direct effects of endotoxin on canine gastric mucosal permeability and morphology in the absence of arterial hypotension were evaluated. Male and female mongrel dogs were anesthetized and the fundic section of the stomach was removed and placed in a single- or double-lumened Leucite chamber. Mucosal bathing solutions of isotonic HCl and isosmotic mannitol were used singly in the single chamber experiments and together, one in each chamber, in the double chamber experiments. *E. coli* endotoxin (0.1 ml/min) was infused continuously into the artery supplying the chambered gastric segment; during control periods, normal saline was infused. Endotoxin infusion produced a profound change in the mucosal appearance, from bright, uniform red during the control periods to mottled, pale-white during endotoxin infusion. Gross erosions occurred in 4/13 mucosae bathed with 0.15 N HCl within 1 hr of infusion of endotoxin in the absence of arterial hypotension. Histological changes seen in most experiments included a release of mucus from the surface epithelial cells and elevation of the epithelium from the basement membrane. In more advanced lesions, severe injury extended into the gastric glands and surrounding connective tissue with cellular necrosis. In spite of gross and microscopic gastric mucosal injury, no significant change was seen in hydrogen ion back diffusion or sodium efflux. These observations suggest that gastric mucosal injuries can occur in endotoxemia without systemic arterial hypotension and that anatomical mucosal injuries are not associated with the destruction of the hydrogen-sodium permeability barrier.

5208 CYTOTOXICITY OF VINBLASTINE AND VINCRISTINE TO PANCREATIC ACINAR CELLS.

(E.) Nevalainen, T. J. (Dep. Pathol. Anat., Univ. Turku, Finland). *Virchows Arch. Zellpathol.* 18(2):119-127, 1975.

The effects of the Vinca alkaloids vinblastine and vincristine on the ultrastructural integrity of the murine exocrine pancreas cells were studied. Vincristine (20 mg/kg) or vinblastine (40 or 200 mg/kg) dissolved in saline was given as a single i.p. injection to male and female BALB/c mice; nontreated mice served as controls. The animals were killed 1, 3, 5, or 24 hr or 4 days after drug treatment and small pieces of the pancreas were prepared for electron microscopic examination. Fatty liver was found in all animals within 24 hr after treatment with either drug, and there were scattered foci of cell necrosis within 24 hr and marked loss of acinar cells and pancreatic atrophy within 4 days after drug administration. In animals killed after 1 hr, the acinar cells were slightly swollen and some areas of the rough endoplasmic reticulum were vesiculated. The number of autophagic vacuoles in the acinar cells increased progressively between 3 and 5 hr after treatment, the Golgi apparatus being hypertrophied at these times. Mitochondria and portions of the rough endoplasmic reticulum were identified within the autophagic vacuoles. The zymogen granules appeared normal but were decreased in number. These changes were more pronounced after 24 hr and 4 days, necrotic and disintegrating acinar cells being found at both times. It is concluded that the vinca alkaloids caused autophagy and degeneration in the pancreatic acinar cells and that their inhibitory effect on pancreatic enzyme secretion might depend partly or solely on their cytotoxic action.

5209 MORPHOLOGICAL EFFECTS OF INTRAPERITONEAL OILY FATTY ACIDS ON THE INTESTINE AND PERITONEUM OF RATS.

(E.) Wagner, R.; Oehlert, W. (Dep. Pathol., Univ. Freiburg, Germany). *Beitr. Pathol.* 154(3):281-292, 1975.

The effects of the administration of oily fatty acids on the intestinal mucosa was studied in 133 rats. Sesame oil DAB 6 was injected i.p. daily in amounts of 3.3 ml/kg and 6.6 ml/kg; 43 received 3.3 ml/kg p.o. The rats were sacrificed at various time intervals, blood samples were taken, and tissues were prepared for histologic study. Other groups of rats received single i.p. injections of 5 ml, 10 ml, or 20 ml sesam oil; four rats received 3 ml daily for 5 days. They were sacrificed on various days from day 1 to day 75. No pathological changes were found in animals treated p.o. After 68-100 days of continuous daily i.p. injections, changes in the small intestinal mucosa were observed: structural villous alterations with shortening, broadening and fusion of villi, fatty vacuolization of epithelia, dilation of lymphatics and mesenchyme activation of the villous stroma with occurrence of large, PAS-positive histiocytes. The most impressive structural changes resulted from long-term low dosage or short-term high dosage of oil. The results suggest that the oil-induced granulomatous proliferative-inflammatory process of the peritoneum could be regarded as a precursor and mediator of the changes, and that absorptive overload of the peritoneum and overcharge of the mesenteric lymph drainage are pathogenic factors in the development of mucosa alteration leading to disturbed villous microcirculation and insufficient supply to the enterocytes.

5210 PERIBILIARY PORTAL SYSTEM IN THE MONKEY LIVER AS EVIDENCED BY THE INJECTION REPLICA SCANNING ELECTRON MICROSCOPE METHOD.

(E.) Murakami, T.; Itoshima, T.; Shimada, Y. (Okayama Univ. Sch. Med., Japan). *Arch. Histol. Jpn.* 37(3): 245-260, 1974.

The peribiliary plexus and its efferent vessels in the monkey liver were studied using a method consisting of plastic casting and scanning electron microscopy combined with microdissection. The methyl methacrylate blood vascular casts of a male rhesus monkey liver and the kidney of a male crab-eating monkey were used. It was demonstrated that the peribiliary blood vascular plexus received the afferent vessels from the hepatic artery and emitted the efferent vessels directly draining into the hepatic sinusoids. The study also confirmed that the route to the sinusoids *via* the peribiliary plexus is completely isolated from the route of the portal vein as well as the arterial pathway to the sinusoids. The findings support the classical view of the "radicular portal veins" and show that the efferent vessels of the peribiliary plexus are distributed as if they cover deficiencies of the portal supply to the sinusoids.

5211 MACROMOLECULAR CONFORMATION OF THE COLON MUCUS AS REVEALED BY DETECTION OF ANISOTROPIC PHENOMENA. *(E.)* Vidal, B. C.; Mello, M. L. S. (Inst. Biol., State Univ. Campinas, Brazil). *Ann. Histochim.* 19(2):151-156, 1974.

Macromolecular components of rat colon mucus were studied after staining with toluidine blue solution (pH 4.0) and anisotropical phenomena were also investigated. The mucus was found to be metachromatic and displayed anisotropic phenomena; dichroism was visually observed, which was negative at wavelengths 490-620 nm. The anomalous dispersion of the birefringence showed an inflection point at a wavelength near that of the linear dichroism maximum; thus it was considered a Cotton effect-like phenomenon. The observations suggest a helical conformation for the acid mucopolysaccharides of the mucus and that structural conditions and/or patterns of molecular orientation of the acid mucopolysaccharides can vary in different tissues.

5212 PROLIFERATIVE PATTERNS IN THE MOUSE JEJUNAL EPITHELIUM AFTER FRACTIONATED ABDOMINAL X-IRRADIATION. *(E.)* Lesher, S.; Cooper, J.; Hagemann, R.; Lesher, J. (Allegheny Gen. Hosp., Pittsburgh, Pa.). *Curr. Top. Radiat. Res.* 10(3):229-261, 1975.

Cell proliferation was studied in the jejunal epithelium of mice exposed to fractionated abdominal x-irradiation. Lightly anesthetized male C57Bl/6J mice were exposed to x-irradiation at a dose level of 300 R; the upper portion of each animal was lead shielded. The radiation exposures were repeated 2, 4, 6, or 9 times, with intervals of 6, 12, 24, 48, or 96 hr separating the exposures. The crypt squash technique was used to measure labeled nuclei and mitotic figures/crypt 1-96 hr after the final exposure, and cell cycle times including estimates of G_1, S, G_2, and M were made 12 and 24 hr after the final exposure. The damage-repair-recovery pattern, i.e., increase in the size of the proliferative population and acceleration of the generation cycle, was similar after single (previous data) and fractionated exposures. However, there were quantitive differences between various fractionation regimens. Overshoot in labeled nuclei/crypt and mitotic figures/crypt following 2 or more exposures was less than after 1 exposure, and the G_2 block decreased as the number of fractions increased. The number of 300 R exposures which could be tolerated was dependent on the time interval between exposures. Total cell production through 9 successive exposures was estimated to be, in percent of controls, 15% (12 hr interval), 34% (24 hr interval), and 64% (48 hr interval). As a result, death followed depression of the total cell production to 15% of the control levels for 4 days (12 hr fractions), to 34% of control levels for 8 days (24 hr fractions), and to 64% of control levels for 16 days (48 hr fractions). Thus, both the degree and the duration of depressed proliferative activity are critical factors in the intestinal response to fractionated treatment. Because of its great potential for compensatory hyperplasia following injury, the intestinal epithelium is capable of recovery from extensive damage provided that critical levels of crypt depletion have not occurred and that sufficient time is allowed for the acceleration in proliferative activity. The compensatory recovery potential is maintained over a large number of exposures.

5213 STUDIES ON A FRACTION OF HUMAN GASTRIC MUCOSA CONTAINING INTRINSIC FACTOR ISOPROTEINS TYPICAL OF MUCOSA. *(E.)* Grasbeck, R.; Marcoullis, G. (Inst. Med. Res., Helsinki, Finland). *Scand. J. Clin. Lab. Invest.* 35(1):13-18, 1975.

A mucosal fraction containing isoproteins of the vitamin B_{12}-intrinsic factor complex with high isoelectric points (pH 5.05-6.52) was isolated from 15 resected stomachs. This fraction (B_{12}-N) was labeled with ^{58}Co-vitamin B_{12}, partially purified by DEAE-cellulose chromatography, and studied by electrofocusing, gel filtration, ultracentrifugation, immunologic procedures, and the Schilling test. The molecular weight of the fraction was about 2000 daltons smaller than gastric juice B_{12}-intrinsic factor. The fraction possessed immunological and biological intrinsic factor activity. When the purified B_{12}-N was mixed with antiserum from a patient with pernicious anemia and subjected to Sephadex G-150 filtration, the radioactivity was totally removed. After administration of 1 μg radioactive vitamin B_{12} bound to the N-component, the fraction of the p.o. dose excreted in the urine of this patient in 2 days was 10.8% compared with 1.1% of unbound vitamin B_{12} (1 μg). Neuraminidase digestion of the gastric juice vitamin B_{12}-intrinsic factor complex produced a biologically active product containing the high pI isoproteins typical of mucosa. Thus, the high pI fraction is deficient in sialic acid and apparently consists of material not yet ready to be secreted. Since sialic acid does not appear to be a biologically active part of the intrinsic factor molecule, it is possible that sialic acid must be removed before intrinsic factor can act on ileal receptors. Although sialic acid-deficient intrinsic factor possessed immunological activity, it is possible that sialic acid-deficient intrinsic factor molecules play a role in initiating intrinsic factor autoantibodies in connection with mucosal inflammatory processes.

5214 ON THE CELLULAR DISTRIBUTION OF SUCRASE AND ENTEROKINASE IN DIFFERENT POPULATIONS OF RAT INTESTINAL EPITHELIAL CELLS ISOLATED BY A VIBRATION METHOD. *(E.)* Schneider, R.; Troesch, V.; Hadorn, B. (Unit Gastro-Enterol., Clin. Univ. Pediatr., Berne, Switzerland). *Biol. Gastroenterol. (Paris)* 8(1):11-20, 1975.

The cellular distribution of protein, enterokinase, and sucrase was studied in isolated rat intestinal epithelial cells. Using a modification of Harrison and Webster's vibration technique, four different populations of cells were obtained from fasted male Wistar DA rats. Fractions 1 and 2 were harvested from the villus, fraction 3 was obtained from the villus-crypt junction, and fraction 4 was obtained from the crypts. The cells were incubated with trypsin or suspended in EDTA, sonicated, treated with glycodeoxycholate, and dialyzed. The morphology of the small intestinal mucosa before and after removal of the four cell populations was also studied, as was the appearance of the isolated cells. The specific activity of sucrase was significantly and reproducibly different in these fractions, showing the highest specific activity in the cells from the tip of the villus and a steady decrease in activity toward the crypts. There was only a small scatter of results so that the sucrase activity served as a marker for the different cell populations. Enterokinase showed a similar cellular distribution but the scatter of results was much greater and the activities in the various fractions did not always differ significantly. When expressed as percent of total activity, fraction 4 (immature enterocytes) contained more enterokinase than sucrase. When determined in the presence of glycodeoxycholate, there was a 10-fold increase in enterokinase activity. The effect of glycodeoxycholate was due in part to solubilization of the enzyme and in part to an activation of the system enterokinase-trypsinogen. The sucrase activity was not affected by the addition of glycodeoxycholate or preincubation with trypsin. The results suggest that enterokinase is differentiated earlier in the life cycle of the enterocyte than is sucrase.

5215 STRUCTURE OF RAT BILE CANALICULI AS REVEALED BY SCANNING ELECTRON MICROSCOPY. *(E.)* Motta, P.; Fumagalli, G. (Med. Coll., Univ. Rome, Italy). *Anat. Rec.* 182(4):499-514, 1975.

Topographic details of the surface structure of the rat liver bile canaliculus were studied by scanning electron microscopy. Liver tissue from five healthy, young adult rats was perfused with a Tyrode solution and then with 2.5% glutaraldehyde in cacodylate buffer solution. Small pieces of liver were subsequently excised, immersed in the same fixative, and dehydrated prior to microscopic examination. The bile canaliculi appeared as half tubules carved out of the surface of the hepatocytes. In many cases, the bile channel was observed to bifurcate to form two or three long branches running on the same face of the cell. Some of the canaliculi showed a tortuous course with frequent lateral sacculations and/or very short branches; of the lateral branches, some were large and appeared similar to the short lateral branches of the bile canaliculus, while others were smaller and arose obliquely from the subjacent cortical areas of the hepatocyte cytoplasm. The latter aspect was more easily observed in stereo views which showed narrow intracellular projections bordered with a few microvilli opening into the lumen of the acutal intercellular bile canaliculus. Zones measuring up to 5.0 μ in width between the space of Disse and the bile channel were frequently observed. The narrowest of these (0.1 μ) appeared to represent zones where the intercellular clefts arising from the subendothelial space of Disse and its recesses came into close contact with the wall of the bile canaliculus; direct communication between these spaces was not observed. The lateral sacculations observed in some of the bile canaliculi probably correspond to short intracellular branches of the canaliculi.

5216 ENDOCRINE CELLS IN THE HUMAN STOMACH: OPTICAL AND ULTRASTRUCTURAL STUDY IN NORMAL SUBJECTS AND IN SOME PATHOLOGICAL CONDITIONS. *(Fr.)* LeBodic, M. F.; LeBodic, L.; Lefranc, G.; Mussini-Montpellier, J.; Pradal, G.; Tusques, J. (Fac. Med., Nantes, France). *Ann. Anat. Pathol. (Paris)* 19(4);353-370, 1974.

Samples of gastric mucosa obtained from four normal subjects, four patients with gastric ulcers and nine patients with various digestive disorders were used to study human endocrine cells. Based on histochemical and ultrastructural analysis, six distinct types of endocrine cells were found in the human stomach: 1) serotonin cells, exhibiting characteristic yellow fluorescence and containing dense polymorphic granules; 2) enterochromaffin-like cells, essentially located in the fundus; 3) gastrin cells of antropyloric localization characterized by the uneven density of secreting granules; 4) gastrointestinal D cells morphologically related to D cells of islands of Langerhans; 5) infrequent A cells and; 6) "small granule" cells, found more frequently and corresponding to Sasagawa type III cells. Pathological findings in ulcer patients showed a marked decrease in endocrine cells, especially in gastrin cells of the antral mucosa, and the appearance of a large number of very dark endocrine cells which were not found in normal mucosa. Pathological findings in the other patients were too varied to draw valid conclusions, but a large number of dark endocrine cells were also observed in these cases.

ABSORPTION-EXCRETION-TRANSPORT

5237 THE EFFECT OF VITAMIN A DEFICIENCY ON CELLULAR MEMBRANE PERMEABILITY OF SMALL INTESTINE MUCOSA. *(Ukr.)* Leutskyi, K. M.; Baran, M. M. (Dep. Biochem., Univ. Chernivtsi, USSR). *Ukr. Biokhim. Zh.* 46(1):105-109, 1974.

To elucidate the mechanism of biological functioning of vitamin A, the effect of vitamin A deficiency on the permeability of cellular membranes of small intestine mucosa, and on the intra- and extracellular content of Na, K and water, was studied. Experiments were performed on white rats with initial weight of 50 g, fed on a vitamin A-free diet; the control animals were given daily 250 MU of acetic form of vitamin A. The results showed that A-avitaminosis leads to the increase in membrane permeability of the small intestinal mucosa, to the increase of total and intracellular content of Na ions, to the decrease of total and intracellular content of K ions (thus effecting transmembrane gradient of Na), and to the increase of total and extracellular, but to the decrease of intracellular, content of water.

5238 INTESTINAL ABSORPTION OF CYTIDINE DIPHOSPHATE CHOLINE AND ITS CHANGES IN THE DIGESTIVE TRACT.

(E.) Yashima, K.; Takamatsu, M.; Okuda, K. (Kurume Univ. Sch. Med., Japan). *J. Nutr. Sci. Vitaminol.* 21(1):49-60, 1975.

The intestinal absorption and metabolism of $^{14}CH_3$ and C_5 pyrimidine ^3H-labeled CDP-choline following gastric instillation were studied in fasted, anesthetized Wistar rats. After 3 hr, only 5% of the ^{14}C and 15% of the ^3H dose remained in the gut. Hepatic uptake reached a maximum after 2-3 hr. Little to no radioactivity was found in heart, brain, pancreas or urine. Chromatographic analysis of gastric contents 30 min after ^{14}C-CDP-choline instillation showed radioactivity primarily in the CDP-choline fraction whereas intestinal washings showed label primarily in the choline fraction. Label following ^3H-CDP-choline instillation was found in gastric CDP-choline and intestinal cytodine. One-half of acid soluble ^{14}C was located in hepatocyte CDP-choline, choline phosphate and choline while most of the ^3H was in CMP and cytidine with some in CDP-choline and CDP. These results indicate that CDP-choline is broken down in the intestine to choline and cytidine which are transported and phosphorylated by the intestinal mucosa. The relatively small amounts of $^{14}CO_2$ appearing in expired air (14%) and urine (2%) indicate that only a small amount of choline is completely broken down.

5239 DEPRESSION OF JEJUNAL DIPEPTIDE TRANSPORT BY PYRIDOXINE DEFICIENCY IN THE RAT.

(E.) Gupta, V. J.; Edwards, K. D. G.; Asatoor, A. M. (Sydney Hosp., Australia). *Aust. J. Exp. Biol. Med. Sci.* 53(1):89-92, 1975.

The intestinal absorption of three dipeptides and a dicarboxylic acid dipeptide differing in mechanisms of membrane transport was studied *in vivo* in 20 fasted, anesthetized vitamin B_6-depleted and B_6-sufficient male Sprague-Dawley rats. Absorption from an isolated 5 cm section of distal duodenum and upper jejunum was significantly slowed by 50-60% in B_6-depleted animals compared to B_6-sufficient rats. These results confirm previous ones in which decreased intestinal absorption of L-alanyl-L-phenylalamine glycylglycine and L-leucyl-L-tyrosine was found in B_6-depleted rats. Analysis of variance regression lines for dipeptide and amino acid transport in the present system provided support for the concept that dipeptide transport, like amino acid transport, is non-selectively depressed by B_6 deficiency. The results further suggest that both dipeptide and amino acid transport are mediated by a common step which is B_6-dependent.

5240 DIPEPTIDE TRANSPORT IN ISOLATED INTESTINAL BRUSH BORDER MEMBRANE.

(E.) Sigrist-Nelson, K. (Lab. Biochem., Fed. Inst. Technol., Zurich, Switzerland). *Biochim. Biophys. Acta* 394(2):220-226, 1975.

The transport of glycyl-L-leucine into isolated brush border membrane vesicles was studied in Sprague-Dawley rats. Highly purified brush border membranes from isolated epithelial cells of the rat small intestine were incubated in media containing mannitol, buffer, $MgSO_4$, and (1-^{14}C)glycyl-L-leucine, glycyl-L-(U-^{14}C)leucine, (2-^3H)glycine, and/or L-(4,5-$^3H_2$)-leucine. At equilibrium, the uptake values for glycyl-L-leucine (labeled in the glycine and leucine moiety), glycine, and L-leucine were the same; the uptake of both labeled species of dipeptide being similar, while the time courses for glycine and L-leucine were markedly different. Na^+ stimulated L-leucine transport, had a lesser effect on transport of the dipeptide and did not affect glycine uptake. When the membranes were incubated with the radioactive dipeptide, 80% of the initial radioactive content was dipeptide and 20% was glycine; after 5 min, however, 95% of the radioactivity was in the form of glycine and only 5% was in the form of dipeptide. The uptake of glycyl-L-leucine was inhibited by other dipeptides, particularly leucyl and alanyl peptides, but was unaffected by glycine and L-leucine. Glycyl-L-leucine stimulated the uptake of glycine and L-leucine, the stimulatory effect increasing with time. The data support the concept that glycyl-L-leucine is primarily transported intact across the brush border membrane by a specific mechanism differing from that involved in amino acid transport.

5241 A COMPARATIVE STUDY ON THE EFFECTS OF DIFFERENT BILE SALTS ON MUCOSAL ATPase AND TRANSPORT IN THE RAT JEJUNUM IN VIVO.

(E.) Guiraldes, E.; Lamabadusuriya, S. P.; Oyesiku, J. E. J.; Whitfield, A. E.; Harries, J. T. (Inst. Child Health, London, England). *Biochim. Biophys. Acta* 389(3):495-505, 1975.

Closed-loop and perfusion techniques were used to study the effects of deoxycholate, taurocholate and cholate on mucosal ATPase and transport activity in the rat (Wistar strain) jejunum. In the closed-loop experiments, a 25-min absorptive period was used, while in the perfusion studies the infusate flow rate was 0.2 ml/min. In the closed loops, 5 mM deoxycholate selectively inactivated (Na^+ + K^+)-ATPase, and a net secretion of Na^+ induced by 2.5 mM deoxycholate was due to reduced lumen to plasma flux of the ion. Deoxycholate (2.5 mM) also markedly inhibited 3-O-methylglucose transport. The luminal disappearance rates of deoxycholate (60.5%/g) greatly exceeded those of taurocholate (4.3%/g). In the perfusion studies, 1 mM of deoxycholate induced a net secretion of water, Na^+ and Cl^- and inhibited active glucose transport; "total" ATPase, (Na$^+$ + K$^+$)-ATPase and Mg^{2+}-ATPase were also inhibited. At higher concentrations (5 mM), deoxycholate stimulated Mg^{2+}-ATPase activity. Taurocholate and cholate had no effect on transport or (Na$^+$ + K$^+$)-ATPase, and the activities of mucosal lactase, sucrase, and maltase were not affected by 1 mM deoxycholate, taurocholate, or cholate. The mean disappearance rates of deoxy(^{14}C)cholate, cholate, and taurocholate from the intestinal lumen were 50.0%, 30.0%, and 17.7%/g/min. The results suggest that deoxycholate inhibits sodium-coupled glucose transport *via* inhibition of (Na$^+$ + K$^+$)-ATPase at the lateral and basal membranes of the epithelial cells, rather than from an effect at the brush-border membrane level. (Na$^+$ + K$^+$)-ATPase may play a fundamental role in the physiology of intestinal transport, and inhibitory substances may be important in the pathophysiology of certain types of diarrhea.

5242 A GLUCOSE-STIMULATED NONELECTROGENIC SODIUM PUMP IN ILEAL REMNANTS AFTER JEJUNECTOMY.

(E.) Tilson, M. D.; Clifford, B. (Yale Univ. Sch. Med., New Haven, Conn.). *J. Surg. Res.* 13(4):405-408, 1975.

To determine whether "jejunization" of ileal transport processes may occur after proximal resection, the glucose dependence of sodium transport and the transmural potential differences (PDs) were studied in ileal remnants after jejunectomy in adult Sprague-Dawley rats. Fourteen to 21 days after jejunectomy or sham jejunectomy, an isolated distal ileal segment was perfused with test solutions containing mannitol or glucose. Effluent samples were collected at 30-min intervals and the PD was measured every 5 min. The PD of normal ileum increased from 6.44 with mannitol to 7.70 after perfusion with glucose solution. The PD of ileum from the jejunectomized rats decreased from 4.86 with mannitol to 4.6 with glucose, the mean PD of glucose-stimulated normal ileum being significantly greater. The net sodium flux increased nonsignificantly after glucose stimulation in normal animals, the glucose-stimulated increase being significant in the jejunectomized animals. Net Na absorption was a linear function of water flux in both the normal and jejunectomized animals. These observations are consistent with the hypothesis that the transport process of the adapted ileal remnant may begin to imitate those characteristics of the resected segment, a process which has been termed "jejunization."

5243 THE ACTIVATION OF INTESTINAL BRUSH BORDER SUCRASE BY ALKALI METAL IONS: AN ALLOSTERIC MECHANISM SIMILAR TO THAT FOR THE NA$^+$-ACTIVATION OF NONELECTROLYTE TRANSPORT SYSTEMS IN INTESTINE.

(E.) Mahmood, A.; Alvarado, F. (Sch. Med., Univ. Puerto Rico, San Juan). *Arch. Biochem. Biophys.* 168(2):585-593, 1975.

A model for the activation of intestinal brush border sucrase by alkali-metal ions was applied to new data on the mechanism of the Na$^+$-activation of brush border sucrase from the guinea pig intestine. The model describes the activation by alkali-metal ions by an allosteric, noncompulsory mechanism involving two distinct sites: one for sucrase and another for the metal activator. In the present experiment, sucrase activity was determined with glucose oxidase-peroxidase in guinea pig brush borders incubated in 4 mM Li-succinate containing 20 mM sucrose and Na$^+$, K$^+$, and/or Li$^+$. Both Na$^+$ and K$^+$ activated the guinea pig sucrase, but K$^+$ had 10 times more affinity for the metal activator site; Li$^+$ was inert. Values for the dissociation constants for the interaction of sucrase with sucrose, Na$^+$, or K$^+$ were calculated for these data and for previously recorded data for the rat and hamster. Qualitatively, the activation of sucrase by alkali metal ions was similar to that described for the Na$^+$-activation of amino acid and sugar transport in the intestine. However, the Na$^+$-binding site in the two systems was apparently quite different. In the guinea pig, the Na$^+$-dissociation constant was on the order of 10^{-3} M for sucrase, about two orders of magnitude smaller than that for transport. Also, K$^+$ was a strong activator of guinea pig sucrase, but was an inhibitor of intestinal sugar transport. It is concluded that the brush border sucrase and sugar carrier in the intestinal sugar transport system do not share a common Na$^+$-binding site.

5244 ABSORPTION OF TWO PROLINE CONTAINING PEPTIDES BY RAT SMALL INTESTINE IN VIVO. *(E.)*

Lane, A. E.; Silk, D. B. A.; Clark, M. L. (St. Bartholomew's Hosp., London, England). *J. Physiol.* 248(1):143-149, 1975.

The *in vivo* intestinal absorption of glycyl-L-proline and L-prolyl-glycine, two dipeptides which are poorly hydrolyzed *in vitro* by brush border peptide hydrolases, was investigated in adult male Wistar rats. A steady-state perfusion technique was used and jejunal absorption was compared with ileal absorption using the rates of absorption of constituent amino acids from dipeptide and equivalent equimolar amino acid solutions. Glycine and proline were absorbed at the same or faster rates during perfusion of 10 mM glycyl-L-proline than during the perfusion of its equivalent equimolar amino acid solution. Conversely, the two constituent amino acids were absorbed at slower rates during the perfusion of 10 mM L-prolyl-glycine than during perfusion of its equivalent amino acid solution. As expected, very low concentrations of free amino acids were detected during the jejunal dipeptide perfusions, while higher concentrations were detected during the ileal perfusions. The addition of 40 mM L-prolyl-glycine to the 10 mM glycyl-L-proline solution did not affect the rates of disappearance of glycyl-L-proline. The addition of 40 mM of glycyl-L-proline to 10 mM L-prolyl-glycine, however, had a significant inhibitory effect on the disappearance of L-prolyl-glycine. It is concluded that whereas glycyl-L-proline and L-prolyl-glycine are absorbed predominantly intact in the jejunum, ileal absorption probably involves both direct peptide uptake and absorption of liberated amino acids by specific amino acid transport systems.

5245 MORPHOLOGICAL AND FUNCTIONAL EFFECTS OF BILE SALTS ON RAT COLON. *(E.)* Saunders, D. R.; Hedges, J. R.; Sillery, J.; Esther, L.; Matsumura, K.; Rubin, C. E. (Dep. Med., Univ. Washington, Seattle). *Gastroenterology* 68(5):1236-1245, 1975.

The effects of conjugated and unconjugated bile salts on the morphology of and net water transport across the rat colon were measured *in vivo*. Colonic segments, consisting of the large intestine distal to the cecum, were infused in an isoperistaltic direction in anesthetized male Sprague-Dawley rats. The test infusates consisted of buffered saline, delipidated rat bile (7-9 mM bile salts), 1-3 mM deoxycholate, or 2.5-10 or more mM taurocholate. Epithelial alteration in the colonic absorptive cells was equivocal and water absorption was uninhibited during infusions of delipidated rat bile, 1 mM deoxycholate, or of concentrations of taurocholate less than 10 mM. In contrast, 3 mM deoxycholate and taurocholate in concentrations of 10 mM or greater caused severe alterations in the colonic epithelium as seen under the light microscope, and inhibited water absorption. Under the electron microscope, the absorptive cells covering the colonic mucosal surface of segments infused with higher concentrations of deoxycholate or taurocholate were reduced in height and many showed structural signs of cell injury. Dilation of intercellular spaces was an inconsistent finding which correlated poorly with the rate of net water transport. The results suggest that in some patients with ileal disease, abnormally high bile salt concentrations in the fecal water would be expected to inhibit water absorption and perhaps to alter the structure of colonic absorptive cells.

5246 FATTY ACID INHIBITION OF WATER ABSORPTION AND ENERGY PRODUCTION IN THE HAMSTER JEJUNUM. *(E.)* Gaginella, T.; Bass, P.; Olsen, W.; Shug, A. (Sch. Pharm., Univ. Wisconsin, Madison). *FEBS Lett.* 53(3):347-350, 1975.

To determine the mechanism involved in the fatty acid inhibition of intestinal water and sodium absorption, the effects of hydroxylated and nonhydroxylated octadecenoates on intestinal water transport and adenine nucleotide translocase (ANT) activity were studied in nonfasted male Golden Syrian hamsters. Water transport was assessed using everted gut sacs prepared from 12 cm segments of jejunum distal to the ligament of Treitz. The sacs were incubated with continuously gassed mucosal and serosal buffer solutions containing the fatty acids to be tested. ANT activity was measured directly in the homogenates of mucosal scrapings of sacs incubated without polyethylene glycol. Purified mitochondria were also prepared for respiratory studies. Ricinoleate, ricinelaidate, and oleate inhibited ANT activity and water transport, the latter being a stronger inhibitor of ANT and the two former fatty acids being stronger inhibitors of water transport. Elaidate inhibited neither ANT nor water transport. The ANT-specific inhibitor atractylate inhibited ANT activity by about 90%, but inhibited water transport by only 40%. Oleoyl CoA inhibited respiration in the purified mitochondria, inhibition of the coupled state being reversed by the addition of the uncoupler ClCCP; similar inhibitory effects were observed with atractylate. These results indicate that in the intestine, as in other organs, ANT, by controlling the mitochondrial ATP/(ADP + P_i) ratio can influence the regulation of energy-linked cellular metabolism. This in part accounts for the effects of fatty acids on intestinal water absorption.

5247 THIAMINE TRANSPORT ACROSS THE RAT INTESTINE. I. NORMAL CHARACTERISTICS. *(E.)* Hoyumpa, A. M., Jr.; Middleton, H. M.; Wilson, F. A.; Schenker, S. (Vanderbilt Univ. Med. Sch., Nashville, Tenn.). *Gastroenterology* 68(5):1218-1227, 1975.

The characteristics of normal thiamine transport across the intestine were studied in female Sprague-Dawley rats using intact intestinal loops and everted jejunal segments. *In vivo* studies with (^{35}S)thiamine hydrochloride revealed, in all segments of the small intestine, saturation kinetics for low thiamine concentrations (0.06-1.5 μM), with a linear relationship between higher concentrations (2-560 μM) and absorption. Moreover, *in vitro* studies of net transmural flux using everted jejunal sacs demonstrated movement of (^{14}C)thiamine hydrochloride against a concentration gradient only when low thiamine concentrations were used, so that the serosal to mucosal ratio became significantly greater than the initial value of 1. Pyrithiamine (2 μM), dinitrophenol (200 μM), norethylmaleimide (100 μM), and ouabain (100 μM) reduced the net transmural flux of 0.2 μM thiamine. When unidirectional flux across the jejunum was measured, saturation kinetics were again demonstrated for low thiamine concentrations. This phenomenon, however, was abolished by the addition of pyrithiamine, which exerted competitive inhibition on thiamine absorption. Anoxia and sodium lack reduced the intestinal uptake of 0.5 μM thiamine to 58% and 74%, resp., or normal, but did not affect the uptake of 50 μM thiamine. Lowering the temperature led to a fall in thiamine uptake, the reduction being more marked with low thiamine concentrations (Q_{10}, 1.648) than with high concentrations (Q_{10}, 1.127). Stirring the water layer reduced the K_m to 59% of the unstirred value, while the V_{max} and permeability coefficient remained unchanged. Finally, movement of low concentrations of thiamine against an electrical gradient was observed under conditions of electrical short circuiting and zero potential difference; no such effect was seen with high concentrations. These studies suggest that there exists in the rat a dual system of intestinal thiamine transport: at low concentrations, thiamine is absorbed by an active process; and at high concentrations, transport across the intestine is largely a passive movement.

5248 MUCOSAL UPTAKE IN VITRO OF CHOLESTEROL FROM BILE SALT AND SURFACTANT SOLUTIONS. *(E.)* Feldman, E. B.; Cheng, C. Y. (State Univ. New York Downstate Med. Cent., Brooklyn). *Am. J. Clin. Nutr.* 28(7):692-698, 1975.

Cholesterol influx rates were analyzed across rat jejunum from various mixed micellar solutions of conjugated bile salts. Rat jejunal mucosal sheets were exposed for 1-2 min to 10 mM micellar solutions of taurodeoxycholate, dodecylsulfate, Tween 80, or cetyltrimethylammonium bromide containing cholesterol, 0.25 mM. Monoolein and/or oleic acid were variably added. Cholesterol influx was insignificant in all solubilizers without additives. With taurodeoxycholate, addition of monoolein progressively enhanced influx from 13 nM/cm^2/hr to 29 nM/cm^2/hr (0.67-5.4 mM monoglyceride). Oleic acid, 3 mM, was as effective as 5.4 mM monoolein. Oleic acid, 3 mM, added to monoolein, 3 mM, maximized influx (42 nM/cm^2/hr). With cetyltrimethylammonium bromide, monoolein, 0.67 mM, enhanced influx to 13 nM/cm^2/hr, but further additions of monoolein with or without oleic acid had no added effect. Additives had no significant effect on the influx from the other anionic or nonionic surfactants. The results suggest that factors other than cholesterol, monoolein or oleic acid partition, and micellar size may be determinants of sterol influx, such as specific interactions of bile salt and fatty acid or monoglyceride with the plasma membrane.

5249 EFFECT OF PERFUSION RATE ON ABSORPTION, SURFACE AREA, UNSTIRRED WATER LAYER THICKNESS, PERMEABILITY, AND INTRALUMINAL PRESSURE IN THE RAT ILEUM IN VIVO.

(E.) Lewis, L. D.; Fordtran, J. S. (Univ. Texas Health Science Center, Dallas, Tex.). *Gastroenterology* 68(6):1509-1516, 1975.

The effect of perfusion rate on the absorption of glucose, tritiated water, urea and mannitol was studied in the rat ileum *in vivo*. Groups of eight female Sprague-Dawley rats were perfused with a test solution (each containing 5 g/l of polyethylene glycol as a marker). The first series of experiments utilized a partially obstructed intestinal segment. Glucose absorption from a 72 ml glucose solution and tritiated water absorption increased equally at about 7% as perfusion rate was increased from 10 to 100 ml/min. Glucose absorption from a 4 mM solution was increased by 70% as perfusion rate was increased from 10 to 100 ml/min. Mean intraluminal pressure was 2.9 mm Hg at a perfusion rate of 1 ml/min and increased only slightly when the rate was 10 ml/min. With perfusion rates of 100 and 200 ml/min, pressure rose to 7.5 and 17.8 mm Hg, resp. Because mannitol absorption was 0 at all perfusion rates, none of the enhanced glucose absorption rates was attributed to enhanced mucosal permeability, even though intraluminal pressure was increased at higher perfusion rates. Urea absorption was influenced by surface area and by permeability changes, but not by the thickness of the unstirred water layer. The effect of unstirred water layer thickness on the inhibitory effect of sodium replacement by magnesium on glucose absorption from a 4 mM glucose solution was also studied. Inhibition by sodium removal was equal at 1, 10, 100 and 200 ml/min. Experiments in an unobstructed intestinal segment revealed that the major effect of enhanced perfusion rate was to increase mucosal surface area. These data emphasize the need for a surface area marker in studies done to evaluate the effect of perfusion rate on intestinal absorption *in vivo*, and tritiated water absorption seems preferable to maximal glucose transport rates.

5250 IS PHLORIZIN OR ITS AGLYCON THE INHIBITOR OF INTESTINAL GLUCOSE TRANSPORT? A STUDY IN NORMAL AND LACTASE DEFICIENT MAN.

(E.) Blum, A. L.; Haemmerli, U. P.; Lorenz-Meyer, H. (Med. Clin., Stadtspital Triemli, Zurich, Switzerland). *Eur. J. Clin. Invest.* 5(3):285-288, 1975.

The inhibition of intestinal glucose absorption by phlorizin was studied in ten normal and six lactase-deficient human subjects. Small bowel perfusion studies were performed with a 4-lumen tube, which was introduced into the intestine after an overnight fast; the proximal balloon of the apparatus was placed at the beginning of the third part of the duodenum. For the first 80 min, an isotonic solution containing 167 mM of glucose, 77 mM of NaCl, and 10 g/l of polyethylene glycol was perfused at a rate of 10 ml/min; in some subjects, 2 mM of phlorizin were added to this solution during the following 80-min period. Intestinal aspirates were collected throughout the experiment and glucose content was measured using the hexokinase method. During the control period, glucose absorption was 8.57 g/hr in the controls and 9.99 g/hr in the subjects with lactase deficiency. Steady state was not reached in the perfused segments during this period. Following phlorizin administration, there was a rapid reduction in glucose absorption, which reached, at the end of this period, 31.5% of the mean absorption rate before phlorizin in the controls and 33.0% in the lactase-deficient subjects. In normal subjects receiving no phlorizin, the absorption rate remained constant during the second period. The results suggest that phlorizin directly inhibits glucose transport in man and that phlorizin hydrolase is not necessary for this effect.

5251 SUGAR ABSORPTION BY FOETAL AND NEONATAL RAT INTESTINE IN VITRO.

(E.) Bamford, D. R.; Ingham, P. A. (Dep. Zool., Queen's Univ., Belfast, Ireland). *J. Physiol. (Lond.)* 248(2):335-348, 1975.

The development of jejunal sugar absorption by fetal and neonatal rat intestine was studied using an *in vitro* accumulation technique. Jejunal segments from fetal and neonatal rats (aged 5 to 26 days) were incubated for 30 min in 5.0 mM of D-galactose. The highest level of uptake was just before birth and throughout the first week post partum. The integrity of the absorbed sugar was checked by chromatography; no appreciable metabolism of galactose took place during the incubations. When rings of fetal or neonatal intestine were incubated in 2,4-dinitrophenol, significant reductions (101.92 to 66.7 μM/g) in galactose uptake were observed. Before "cut-off" (the time at which the absorption of intact protein ceased), the ileum was significantly more effective in galactose absorption than the jejunum or duodenum. Around "cut-off" the jejunum became the principal site of absorption. The adult pattern of functional localization along the intestine was not fully established until after the third week post partum. The results suggest that variations with respect to age in the distribution or density of the sugar carriers along the intestine, rather than changes in the nature of the carriers themselves, account for the variation in sugar absorption.

5252 THE EFFECT OF RAISING THE CONCENTRATION OF POTASSIUM IN THE BLOOD OR INTESTINAL LUMEN ON THE TRANSPORT OF POTASSIUM IN THE DOG INTESTINE. *(E.)* Hardy-Smith, A.; Shields, R. (Dep. Surg., Univ. Liverpool, England). *Br. J. Surg.* 62(6):455-461, 1975.

The rates of transport of potassium, sodium, and water across the intestinal mucosa of Thiry-Vella fistulas of colon and ileum were studied in four dogs over a period of several months under three conditions: control, following i.v. infusion of potassium (15 mEq) over 30 min, and during variations in the intraluminal concentration of potassium (0.8-16.0 mEq/l). Following i.v. infusion of potassium, the rates of potassium secretion into the colon were usually increased; the rates of sodium and water absorption were either unchanged or decreased. The unidirectional rate of movement of potassium into the lumen increased as the concentration difference across the mucosa increased; the movement of potassium in the opposite direction remained relatively constant. The unidirectional movement of sodium and water into the lumen of the colon also increased but to a lesser extent. The effect on potassium transport in the ileum was not significant. With increase in the intraluminal concentration of potassium, there was a significant decrease in the rate of net potassium secretion in both colon and ileum. The rates of net absorption of sodium and water were not significantly altered. Unidirectional potassium movement into the body increased in all the ileal fistulas. The results suggest that whenever the concentration of potassium in the plasma rises, potassium secretion into the gastrointestinal lumen is increased.

5253 INTESTINAL AMINO ACID ABSORPTION IN VITAMIN D DEPENDENT RICKETS. *(Ger.)* Harmeyer, J.; Martens, H.; Vogelgesang, G. (Physiologisches Inst. der Tierarztlichen Hochschule, D-3000 Hannover, Bischefshofer Damm 15, Germany). *Z. Kinderhoilkd.* 119(4):245-251, 1975.

MOTILITY

5267 SELECTIVE ANTAGONISM OF THE INTESTINAL STIMULATORY EFFECTS OF MORPHINE BY ISOPROTERENOL, PROSTAGLANDIN E_1 AND THEOPHYLLINE. *(E.)* Grubb, M. N.; Burks, T. F. (Univ. Texas Med. Sch., Houston). *J. Pharmacol. Exp. Ther.* 193(3):884-891, 1975.

Studies were undertaken to determine whether treatment with isoproterenol, prostaglandin E_1 and theophylline would inhibit intestinal responses to morphine without interfering with motor responses to acetylcholine. Contractions (induced by graded, intraarterial bolus doses of morphine and acetylcholine) were measured in isolated segments of adult mongrel dog intestine perfused *via* the vasculature with Kreb's solution. Addition of the α- and β-adrenergic receptor agonist, norepinephrine (0.2 μg/ml), to the perfusion solution slightly decreased the magnitude of contractor responses to acetylcholine; responses to morphine were decreased considerably. The pure α-adrenergic receptor agonist, methoxamine (50 μg/ml), and the pure β-adrenergic receptor agonist, isoproterenol (5 μg/ml), produced similar effects. Perfusion of intestinal segments with Kreb's solution containing prostaglandin E_1 (1 μg/ml) or theophylline (180 μg/ml) resulted in marked decreases in responses to morphine but had no significant effects on responses to acetylcholine. Patterns of inhibition similar to those seen with morphine have been previously observed with 5-hydroxytryptamine, which may mediate the intestinal stimulatory effects of morphine. The mild inhibitory effects of methoxamine and isoproterenol on responses to acetylcholine are attributed to actions on neural and possibly non-neural adrenergic receptors. Since isoproterenol, prostaglandin E_1 and theophylline have in common the ability to elevate or maintain intracellular levels of cyclic AMP (cAMP), it is suggested that the intestinal stimulatory effects of morphine may result from 5-hydroxytryptamine-mediated interference with smooth muscle inhibitory actions of cAMP.

5268 INTERACTION BETWEEN ALUMINUM AND CALCIUM IONS IN POTASSIUM CHLORIDE DEPOLARIZED GASTROINTESTINAL SMOOTH MUSCLE. *(E.)* Hava, M.; Hurwitz, A. (Univ. Kansas Med. Cent., Kansas City). *Arch. Int. Pharmacodyn. Ther.* 214(2):213-223, 1975.

The effects of aluminum chloride and lanthanum chloride on gastrointestinal smooth muscle (under varying conditions of depolarization) were described, in order to define the interaction of these trivalent cations with calcium. Isolated colon (2-3 cm portions) from male Sprague-Dawley rats, and segments from guinea pig ileum were used. Aluminum chloride (5×10^{-4} M) abolished the inhibitory effects of papaverine chloride (1.5×10^{-5} M) on contractions of ileum and colon evoked by calcium in Tyrode's solution containing a high concentration of KCl. The inhibitory effects of cocaine hydrochloride (10^{-3} M) and $MgSO_4$ (2×10^{-2} M) were not antagonized. In isolated colon (depolarized by partial exchange of NaCl by 40 mM KCl), $AlCl_3$ decreased the phasic contractions and slowed the onset of tonic contraction during increase of the $CaCl_2$ concentration from 1.8×10^{-3} M to 7.2×10^{-3} M. The increase in spontaneous activity was not blocked by atropine sulfate (10^{-7}-10^{-4} M), but was partially antagonized by 10^{-3} M caffeine and was completely blocked by papaverine chloride (5×10^{-4} M). More than one site of action is proposed for the effects of aluminum on gastrointestinal smooth muscle.

5269 INHIBITION OF SMALL INTESTINAL MUCOSAL AND SMOOTH MUSCLE CELL FUNCTION BY RICINOLEIC ACID AND OTHER SURFACTANTS. *(E.)* Gaginella, T. S.; Stewart, J. J.; Gullikson, G. W.; Olsen, W. A.; Bass, P. (Cent. Health Sci., Univ. Wisconsin, Madison). *Life Sci.* 16(10):1595-1606, 1975.

The effects of ricinoleic acid on the inhibition of net water and on electrolyte transport and intestinal smooth muscle contractile response *in vitro* were compared with the effects produced by two structurally different, anionic surfactants, a non-ionic surfactant and two bile salts. Net water and electrolyte transport from everted hamster (Golden Syrian) gut sacs and contractile activity of electrically-stimulated guinea pig ileum were assessed. Sodium ricinoleate, dioctyl sodium sulfosuccinate, sodium dodecyl (lauryl) sulfate, polysorbate 80, sodium deoxycholate and chenodeoxycholate were found to produce depression of *in vitro* mucosal and smooth muscle cell function. All compounds were effective depressants of both systems at concentrations which were likely to be below their respective critical micellar concentrations. It is suggested that ricinoleic acid may produce its cathartic effect due to its amphipathic nature, possibly by hydrophobic interaction with membrane lipoproteins. Ricinoleic acid and the other surfactants may be acting through a common mechanism.

5270 EFFECTS OF BOMBESIN AND BOMBESIN-LIKE PEPTIDES ON GASTROINTESTINAL MYOELECTRIC ACTIVITY. *(E.)* Caprill, R.; Melchiorri, P.; Improta, G.; Vernia, P.; Frieri, G. (Second Med. Clin., Rome, Italy). *Gastroenterology* 68(5):1228-1235, 1975.

The effects of bombesin and bombesin-like peptides on the electrical activity in the gastrointestinal tract were studied in conscious mongrel dogs. Electrodes were chronically implanted in the intestinal muscle layer at different levels between the stomach and rectum. Bombesin (5, 10, 15, 30 ng/kg/min), COOH-terminal heptapeptide and COOH-terminal octapeptide (20 and 80 ng/kg/min), COOH-terminal nonapeptide (10, 15, 30 ng/kg/min), and litorin (a new natural peptide isolated from the skin of *Litoria aurea*, 10, 20, 30, 40 ng/kg/min were infused for 20 min into the saphenous vein. The effects of the drugs on frequency, amplitude, and rhythm of pacesetter potentials (PP) and incidence of spikes were evaluated. Bombesin significantly increased the frequency of PP in the antrum, duodenum, jejunum, and ileum. In the duodenum and jejunum, the increase in PP frequency showed a linear correlation with the reduction in PP amplitude, the propagation velocity of PP also being clearly reduced. Spikes were not affected in the antrum and ileum, whereas they were abolished in the duodenum and jejunum. In the duodenum, the increase in PP frequency and the slowing down of the propagation velocity were followed by a loss of PP phase lock and the appearance of a characteristic electrical pattern consisting of an irregular sequence of small and slow potentials ("electric disorganization"). The mechanical counterpart was the disappearance of intraluminal pressure activity. In the colon, the effect of bombesin on electrical activity was inconsistent. Neither the COOH-terminal heptapeptide nor the octapeptide of bombesin showed a significant effect on myoelectric activity, whereas the effects of COOH-terminal-nonapeptide and litorin were similar to those of bombesin. Thus, the characteristic electrical changes of PP produced by bombesin appear to be related to the sequence of the 9 amino acids in the COOH-terminal residue of the bombesin molecule.

5271 INHIBITION OF GASTRIC EMPTYING IS A PHYSIOLOGICAL ACTION OF CHOLECYSTOKININ. *(E.)* Debas, H. T.; Farooq, O.; Grossman, M. L. (VA Wadsworth Hosp. Cent., Los Angeles, Calif.). *Gastroenterology* 68(5):1211-1217, 1975.

The relative effects of cholecystokinin (CCK) and gastrin on gastric emptying in the dog were compared to determine whether CCK plays a physiological role in the inhibition of gastric emptying. Dogs were prepared with gastric fistulas, gastric fistulas and chronic pancreatic fistulas, or gastric fistulas and chronic bile fistulas. To stimulate physiological conditions, CCK, OP-CCK (synthetic C-terminal octapeptide CCK), and 20% CCK were administered by continuous i.v. infusion in doses known to be submaximal for pancreatic protein secretion and gallbladder contraction (0.75-3.0 U/kg/hr for CCK, 1.5-6.0 U/kg/hr for 20% CCK, and 63-250 ng/kg/hr for OP-CCK); in addition, L-tryptophan (10-40 mM/liter) was administered to determine the action of endogenous CCK. The effect of endogenously released CCK was studied by measuring the rate of emptying of NaCl solutions in which different concentrations of tryptophan replaced equiosmolar amounts of NaCl, the rate of emptying of the NaCl solution also being measured after exogenous administration of the test drugs. The D_{50}'s of 20% CCK (3 U/kg/hr) and of OP-CCK (125 ng/kg/hr) for inhibition of gastric emptying were about the same as their D_{50}'s for cholecystokinetic and pancreozyminic actions. In contrast, although both pentagastrin and heptadecapeptide gastrin inhibited gastric emptying, the doses required for this action were much higher than the D_{50}'s required for stimulation of gastric acid secretion. Both pure CCK and tryptophan were potent inhibitors of gastric emptying, and both protein secretion and gallbladder contraction were stimulated during tryptophan-inhibited gastric emptying. The results indicate that the inhibition of gastric emptying is attributable to CCK itself and not to an impurity in the CCK preparation. They further indicate that the inhibition of gastric emptying is one of the physiological actions of CCK, while the effect of gastrin is due to a pharmacological action.

5272 THE EFFECTS OF CHRONIC GANGLION BLOCKADE AND CHRONIC CHOLINESTERASE INHIBITION ON THE SENSITIVITY OF RABBIT STOMACH MUSCULARIS TO CHOLINERGIC AND ADRENERGIC AGONISTS. *(E.)* Lefever, G. S.; Green, R. D. (Univ. Illinois Med. Cent., Chicago). *J. Pharmacol. Exp. Ther.* 193(3):739-747, 1975.

The effects of chronic ganglion blockade and chronic cholinesterase inhibition on the sensitivity of the circular muscle from the rabbit stomach fundus to cholinergic and alpha adrenergic agonists were studied. The EC50 values, dissociation constants (K_A values), and efficacies of various agonists were determined in strips of stomach muscularis from control, chlorisondamine-pretreated and disulfoton-pretreated male and female rabbits. Strips from chlorisondamin-pretreated animals were supersensitive to carbachol but normosensitive to phenylephrine; the efficacy but not the K_A of carbachol was affected by this treatment. The dissociation constant (K_B) of atropine was unchanged. Muscle strips from animals treated with disulfoton were subsensitive to phenylephrine but normosensitive to amidephrine and carbachol, both the efficacy and K_A of phenylephrine appearing to be elevated by this treatment. The K_B of phentolamine remained unchanged. The results indicate that the chlorisondamine-induced supersensitivity is the result of a change beyond the level of the cholinergic receptors. The subsensitivity to phenylephrine after disulfoton pretreatment may result, at least in part, from a qualitative change in the alpha adrenergic receptors in the stomach muscularis.

5273 RADIOIMMUNOASSAY FOR MOTILIN. *(E.)* Dryburgh, J. R.; Brown, J. C. (Dep. Physiol., Univ. Br. Columbia, Vancouver, Canada). *Gastroenterology* 68(5):1169-1176, 1975.

A specific radioimmunoassay for the measurement of motilin in the sera of dogs was developed with the use of antisera to porcine motilin raised in guinea pigs. Antisera to the porcine motilin was raised in guinea pigs by multiple injections of both conjugated and unconjugated polypeptide. Alkalinization studies were then performed using sera from fasted chronic dogs with extrinsically denervated pouches of the fundus of the stomach and Mann-Bollman fistulae into the duodenum. The radioimmunoassay procedure employed highly purified ^{125}I-motilin as the tracer; a sensitivity range of 10-320 pg was found. No cross-reactivity was demonstrated with gastric inhibitory polypeptide, secretin, glucagon, gastrin, cholecystokinin-pancreozymin, or vasoactive intestinal peptide. In the dogs with denervated pouches of the fundus of the stomach and Mann-Bollman fistulae, duodenal alkalinization resulted in an increase in the gastric motor activity in the fundic pouch with a corresponding increase in serum motilin, both parameters reaching their maxima within 5 min. These results strongly support the hypothesis that motilin is the peptide released upon alkalinization of the duodenum.

5274 PROPERTIES OF MECHANOSENSITIVE NEURONS WITHIN AUERBACH'S PLEXUS OF THE SMALL INTESTINE OF THE CAT. *(E.)* Mayer, C. J.; Wood, J. D. (Univ. Kansas Med. Cent., Kansas City). *Pfluegers Arch.* 357(1-2):35-49, 1975.

Extracellular techniques of single unit recording were used to study the response patterns of mechanosensitive neurons located within the ganglia of the myenteric plexus of the duodenum and jejunum of the cat. Segments of duodenum and jejunum from adult cats were mounted within chambers and the myenteric plexus was exposed. Action potentials of the mechanosensitive neurons within the ganglia were detected extracellularly, changes in the discharge pattern of the cell being elicited by mechanical distortion of the ganglion. Most recordings were from the periphery of the serosal side of the ganglia. Three different kinds of mechanosensitive neurons were detected within Auerbach's plexus. Neurons classified as fast-adapting mechanoreceptors discharged spikes at the onset of stimulation, and the discharge stopped during a sustained stimulus of constant intensity. Slowly-adapting mechanoreceptors maintained a steady discharge during sustained stimulation at a frequency which was a direct function of the intensity of the stimulus. Tonic-type neurons responded to mechanical stimulation with a prolonged train of spikes which had a consistent pattern from preparation to preparation. Once the tonic-type cells were triggered, the discharge followed a characteristic time course that was unchanged by further increase or decrease in stimulus activity. Tonic-type neurons are probably not first order sensory neurons, but they may be activated by input derived from primary mechanoreceptors. The frequency of discharge of the slowly-adapting mechanoreceptors was increased by histamine; this appeared to be secondary to histamine-induced contractile activity of the musculature.

5275 CONTROL OF GASTRIC EMPTYING BY OSMOLALITY OF DUODENAL CONTENTS IN MAN. *(E.)* Meeroff, J. C.; Go, V. L. W.; Phillips, S. F. (Mayo Clin., Rochester, Minn.). *Gastroenterology* 68(5): 1144-1151, 1975.

Osmoreceptors within the human duodenum were studied and some aspects of their mechanism of action were elucidated. A 500 ml liquid test meal of varying osmolality was introduced *via* gastric tube into 20 fasted male volunteers. Solutions of varying osmolality were also perfused into the duodenum *via* duodenal perfusion tube. Recovery of the nonabsorbable marker, phenol red, from the duodenum was used to measure and time the rate of gastric emptying. The rates of release of cholecystokinin-pancreozymin (CCK-PZ), gastrin, trypsin, and bile fluids were also measured. Gastric emptying was fastest when the duodenal contents were isotonic; nonisotonic duodenal contents (hypotonic and hypertonic) slowed emptying whether these conditions were achieved by nonisotonic duodenal perfusates or by emptying of a nonisotonic test meal. However, nonisotonic solutions in the stomach and jejunum did not slow gastric emptying so long as the duodenal contents were isotonic. Perfusion of the duodenum with 840 milliosmolar sodium chloride produced an insignificant increase in bile acid and trypsin outputs into the duodenum. When a test meal was given while hypertonic duodenal perfusion was continued, bile acid output peaked while the output of trypsin showed a concomitant sharp increase. When the test meal was emptied and its residual was aspirated from the stomach, the duodenal bile acid and trypsin values returned to basal levels. There were no changes in the fasting serum levels of gastrin or CCK-PZ. The results indicate that osmoreceptors, which slow gastric emptying, are present in the duodenum but not in the jejunum or stomach.

5276 EFFECT OF HYPOTHALAMIC, AMYGDALOID AND CINGULATE GYRUS STIMULATION ON COLONIC MOTILITY. *(Ukr.)* Motuznyi, V. A. (Inst. Physiol., State Univ., Kiev, USSR). *Fizol Zh* 19(6):753-759, 1973.

Colonic motility during different functional stages of the gastrointestinal tract was investigated together with the effect of electric stimulation of the hypothalamus, amygdala, and cingulate gyrus on this type of activity. Experiments were performed on dogs with colon fistulas, and four-polar electrodes implanted into the hypothalamus, amygdala, and cingulate gyrus. Data indicate that colonic motility is characterized by phases associated with mixing, intensive absorption of contents, formation of feces and their motion toward the rectum. The effects of electrical stimulation depended on the functional state of the colon and localization of stimulation. Stimulation of the ventromedial hypothalamic nuclei and macro- and microcellular basal amygdaloid nuclei increased colonic motility; stimulation of the posterior hypothalamus inhibited it. Electrical stimulation of the lateral hypothalamic nuclei affected colonic motility (causing contractions) only with current intensity of at least 1.2 millampere. The anterior cingular stimulation produced the proximal colonical motility followed by inhibition or relaxation in the distal colon.

SECRETION AND METABOLISM

5285 ACTION OF GASTRIN ON GASTROINTESTINAL STRUCTURE AND FUNCTION. *(E.)* Johnson, L. R.; Lichtenberger, L. M.; Copeland, E. M.; Dudrick, S. J.; Castro, G. A. (Univ. Texas Med. Sch., Houston). *Gastroenterology* 68(5, Part 1):1184-1192, 1975.

The effects of continuous pentagastrin (6 μg/kg-hr) and histamine (1 mg/kg-hr) infusion on gastrointestinal structure were studied in 12 male Sprague-Dawley rats maintained by i.v. hyperalimentation for 19 days. Compared to six sham-operated controls, i.v.-fed rats had a 3-fold lower antral and an 8-fold lower serum gastrin level; these levels were not affected significantly by continuous pentagastrin infusion. Oxyntic stomach, small intestine and pancreatic weights were reduced by 25%, 50% and 45%, resp., in hyperalimented rats. Weights of nongastrointestinal tract organs (kidneys, spleen and testes) were not affected by hyperalimentation. Pentagastrin infusion significantly increased oxyntic stomach, small intestine and pancreatic weights to levels near to or exceeding those of control, orally-fed animals. Pentagastrin infusion also completely prevented loss of brush border disaccharidase activity in hyperalimented rats. Infusion of histamine at a dose rate producing gastric acid secretion comparable to that produced by pentagastrin infusion failed to increase organ weights or disaccharidase activity in hyperalimented rats. It is thus concluded that pentagastrin prevents the changes in gastrointestinal structure and function caused by the absence of food in the gut and that the trophic action of gastrin is necessary for the maintenance of this functional and structural integrity.

5286 THE RELATIONSHIP OF INTESTINAL FAT TO AN AUGMENTED ACID AND GASTRIN RESPONSE IN DOGS WITH A REVERSIBLE PANCREATIC FISTULA. *(E.)* Hofmann, J. W.; Raih, T. J.; Go, V. L. W.; Wilson, S. D. (Med. Coll. Wisconsin, Milwaukee). *J. Surg. Res.* 18(4):409-415, 1975.

The relationship between duodenal fat and gastrin and acid responses to meals was investigated in mongrel dogs with reversible pancreatic fistulas and Heidenhain pouches. The acid response from the Heidenhain pouches and the serum gastrin response to a standardized meal were determined with the pancreatic fistula closed (pancreatic juice flowing normally into the duodenum) and open (pancreatic juices diverted externally). In a second group of dogs, the response to a test meal was determined during infusion of olive oil (0.38 cc/min) or oleic acid (0.23 cc/min) into the duodenum. The acid response to feeding with the fistula open was significantly greater than with the fistula closed, as was the mean 3-hr integrated gastrin response; the fasting serum gastrin concentrations with the fistula closed did not differ significantly from those with the fistula open. Infusion of either olive oil or oleic acid into the duodenum resulted in a significant inhibition of the meal-stimulated acid output when the pancreatic juices were allowed to drain normally into the duodenum; the acid response recovered more rapidly after olive oil perfusion than after oleic acid. With the fistula opened, only oleic acid infusion significantly inhibited the augmented acid response to a meal; the integrated gastrin response to a meal was not augmented. There were no pathologic changes noted in the pancreas or liver of any of the dogs. The results suggest that the augmented acid and gastrin response to feeding that occurred when the pancreatic juice was diverted externally resulted from an impaired digestion of fats. They support the hypothesis that during a meal, the by-products of fat digestion normally stimulate the release of a hormone from the duodenum and small bowel and that this hormone acts, in part, to inhibit the meal-stimulated release of gastrin from the antrum.

5287 SIMULTANEOUS CHANGES IN PANCREATIC AND GASTRIC SECRETION INDUCED BY ACUTE INTRAVENOUS ETHANOL INFUSION: EFFECTS OF ATROPINE AND RESERPINE. *(E.)* Tiscornia, O. M.; Palasciano, G.; Dzieniszewski, J.; Sarles, H. (Unit Pathol. Dig. Dis., Marseille, France). *Am. J. Gastroenterol.* 63(5):389-395, 1975.

The effect of i.v. ethanol on gastric and pancreatic secretion was studied in dogs, along with the effect of simultaneous atropine or reserpine perfusion. Four dogs were prepared with chronic pancreatic fistulas and Thomas cannulas were inserted into the most dependent segment of the stomach. Four weeks later, the fasted dogs were subjected to continuous i.v. GIH secretin (0.5 CU/kg/hr) and gastrin (6 γ/kg/hr) infusion; i.v. ethanol infusion (1.3 g/kg) was begun when both the gastric and pancreatic secretion rates had reached plateau levels. In some experiments, atropine infusion (1.0 mg/hr) was begun after hormone infusion and before ethanol infusion, and in others, the dogs were treated with reserpine (0.10 mg/kg/24 hr) for 48 hr beginning 72 hr before hormone infusion. Acute i.v. ethanol inhibited the pancreatic secretion of protein (concentration and output) and stimulated gastric acid secretion. Atropine abolished the ethanol-mediated inhibition of pancreatic protein secretion but did not prevent the alcohol-mediated gastric acid stimulation. Reserpine did not modify the ethanol-mediated inhibition of pancreatic secretion, but it did induce a high plateau level of HCl secretion which obscured the presumed ethanol-mediated excitatory influences on the oxyntic cells. The results suggest that the ethanol-mediated inhibitory effects on pancreatic secretion are probably related to the stimulation of inhibitory fibers in the vagi. They also suggest that adrenoceptive receptors are involved in the excitatory effects of ethanol on HCl secretion.

5288 VAGOTOMY IN THE PREVENTION OF ULCERS AFTER PORTACAVAL SHUNT SURGERY IN RATS. *(Ger.)* Schumpelick, V.; Kauffmann-Mackh, G. (Surg. Clin., Univ. Hamburg, Germany). *Dtsch. Med. Wochenschr.* 99(38):1872-1877, 1974.

The effect of an end-to-side portacaval anastomosis on the incidence of stomach ulcers and the volume, pH, and total acidity of gastric juice was studied in male albino rats. The pylorus was ligated in all animals 14 days after shunt surgery or sham operations (laparotomy, clamping off of the vena cava and portal vein for 10 min, and ligation of the pyloric vein). The incidence of stomach ulcers and the area of these ulcers in mm^2/rat were significantly greater in animals with portacaval anastomoses than in sham-operated controls. The pH, volume, and total acidity of gastric juice were also significantly increased after shunt surgery. When rats underwent selective gastric vagotomy before pyloric ligation, neither rats with portacaval anastomoses nor controls developed gastric ulcers, but the pH of gastric juice was still significantly higher after shunt surgery than after sham operation. These findings suggest that development of ulcers in patients with portacaval shunts might be prevented by combining shunt surgery with selective gastric vagotomy.

SECRETION AND METABOLISM

Stomach

5296 THE INTESTINAL PHASE OF GASTRIC SECRETION.

(E.) Kester, R. C. (Ninewells Hosp., Dundee, Scotland). *Ann. R. Coll. Surg. Engl.* 56(5):231-245, 1975.

The kinetics of hormone release were studied following the application of a stimulus to the intestine, in order to pinpoint the time of maximum hormone concentration in portal blood for subsequent isolation of the hormone. Samples of portal blood were obtained from intestinally-fed donor dogs over 15 min, starting at the following intervals after the start of the meal: 15 min (11 animals); 30 min (17); 45 min (10) and 90 min (10). The animals were subjected to antrectomy, splenectomy, construction of a Heidenhain pouch, gastroduodenostomy, and a Roux-en-Y jejunocutaneous fistula. After 3 weeks, an end-to-side portacaval shunt was performed and an indwelling catheter was placed in the portal vein. To assay histamine activity, Heidenhain pouches were constructed in dogs and tests were performed every 4-6 weeks. Weanling pigs were provided with Heidenhain pouches and acid secretory responses were determined at 1/2 hr intervals for a control basal hour and for 4 hr after a standard oral meal. The intestinal phase hormone was released within 30 min of the application of a stimulus and rapidly reached peak concentration in the portal blood. I.v. infusion into a donor dog of active portal plasma from a shunted, intestinally-fed dog stimulated gastric acid secretion after a delay of approximately 1 hr, and required a mean of 1.5 hr to stimulate peak secretion, which suggests that intermediate steps may be necessary before the hormone can effectively stimulate the parietal cell mass. The pig developed portacaval shunt-related gastric acid hypersecretion in response to food comparable to that observed in the dog and in man. There was also a brief delay in gastric acid secretion after administration of crude intestinal extract, again indicating that some intermediate reactions must occur. In addition, it is suggested that pig jejunal mucosa is an appropriate source for isolation of the intestinal phase hormone.

5297 HEPATIC RESECTION AND GASTRIC SECRETION.

(E.) Pinkerton, Jr., J. A.; Adkins, Jr., R. B.; Gobbel, Jr., W. G.; Foster, J. H. (Veterans Adm. Hosp., Nashville, Tenn.). *Am. Surg.* 41(6): 347-351, 1975.

Gastric acid secretion was studied in six dogs with Heidenhain pouches before and after 60-70% hepatectomy. In 5/6 dogs, hepatectomized gastric secretion was decreased 14-70% ($p<0.02$) following a high protein meal. One dog, which showed increased secretion, was found at autopsy to have a gastric stricture at the site of pouch construction. Conventional liver function tests were transiently abnormal in all dogs postoperatively. Autopsy revealed hyperplasia of remaining hepatic tissue but no gastric or duodenal ulceration in all dogs. These results indicate that hepatic tissue remaining after 60-70% hepatectomy is able to detoxify gastric secretagogues in the portal venous blood sufficiently so that gastric acid secretion is not affected.

5298 EFFECTS OF VAGOTOMY ON URECHOLINE MODIFIED HISTAMINE DOSE RESPONSES IN DOGS. *(E.)*

Hirschowitz, B. I.; Hutchison, G. A. (Univ. Alabama Med. Cent., Birmingham). *Am. J. Physiol.* 228(5): 1313-1318, 1975.

Histamine incremental step-dose response studies were performed in nine dogs with gastric cannula and Komarov esophagostomy. Histamine (2-100 μg/kg-hr) in six successive 45 min steps was infused in four separate studies on each dog. In three dogs, step-dose responses were repeated after vagotomy. In both groups of dogs the dose responses were then studied against background i.v. infusions of urecholine (10, 20, 40, and 80 μg/kg-hr). Vagotomy acted as a competitive inhibitor (K_m doubled from 14 to 29 μg/kg-hr, while V_{max} was unchanged), and this effect could be reversed by <10 μg of urecholine/kg-hr. In both groups, increasing backgrounds of urecholine increased the V_{max} from about 14 meq of H^+/30 min to about 23-24 meq/30 min, and decreased histamine K_m from 14 μg/kg-hr to about 1-2 μg/kg-hr. Both changes were log linear. The effects of urecholine on histamine-stimulated H^+ secretion thus showed synergism (decreased K_m) and potentiation (increased V_{max}); the former was interpreted as a cholinergic effect on the parietal cell histamine receptors and the latter as the probable existence of spare cholinergic receptors not normally accessible to histamine. There were no intrinsic qualitative or quantitive differences in these responses between the vagotomized and innervated stomachs. These results support the use of vagotomy to reduce gastric secretion in patients with duodenal ulcer.

5299 SIGNIFICANCE OF GASTRIC SECRETORY CHANGES IN THE PATHOGENESIS OF STRESS ULCERS.

(E.) Hase, T.; Anderson, P. R.; Mehlman, B. (Walter Reed Army Med. Cent., Washington, D.C.). *Am. J. Dig. Dis.* 20(5):443-449, 1975.

Gastric secretory patterns, plasma corticosterone levels and blood glucose concentrations were analyzed in fasted, rotationally stressed (60 rpm, 2 hr) male albino rats 3 hr after pyloric ligation. Gastric secretion was highest in controls, intermediate in stressed rats that developed ulcers, and lowest in stressed rats that did not develop ulcers. Neither high nor low gastric secretion correlated with stress-ulcer formation. When initial mucosal ischemia and secretory inhibition, which occurred in all stressed rats, were considered, those that developed ulcers manifested gastric hypersecretion when compared with those that did not develop ulcers. Mean plasma corticosterone was highest in stressed rats that developed ulcers, next highest in stressed rats that did not develop ulcers, and lowest in control rats. Compared with normal rats, mean blood glucose was lowest in stressed rats and highest in controls. Hypoglycemic changes were more marked in stressed rats that developed ulcers than in stressed rats that did not develop ulcers. It is suggested that focal mucosal ischemic changes in the presence of hypoglycemia and resultant gastric hyperacidity favor ulcer formation in stressed animals.

5300 OXYGEN TENSION OF THE CANINE GASTRIC MUCOSA UNDER THE INFLUENCE OF VASOACTIVE AND ACID STIMULATING AGENTS AND FOLLOWING VAGOTOMY.

(E.) Hartel, W.; Alken, P.; Linder, M. M. (Surg. Hosp. Infirm., Northwest Frankfurt am Main, Germany). *Bull. Soc. Int. Chir.* 33(5-6):417-421, 1974.

As a measure of microcirculation, oxygen tension was determined in male and female mongrel dogs under the influence of various pharmacologic agents and vagotomy. Fasted, anesthetized animals were subjected to a subdiaphragmatic total vagotomy or were injected i.v. with norepinephrine (2.5 and 5 μg/kg), naftidrofuryl (2-3 mg/kg), or pentagastrin (0.5-5 μg/kg). Central venous and arterial blood pressure and oxygen tension from the gastric antral mucosa were continuously recorded. I.v. norepinephrine caused a short but marked drop in the gastric mucosal oxygen tension, while naftidrofuryl increased the gastric mucosal oxygen tension in spite of a fall in the arterial blood pressure. Pentagastrin caused a temporary rise in oxygen tension followed by a more prolonged decrease. Vagotomy produced a moderate and more persistent drop in the mucosal oxygen tension. It is suggested that the naftidrofuryl-induced rise in mucosal oxygen tension was most probably caused by vasodilatation or, possibly, by an inhibition of cellular metabolism. The effects of pentagastrin can be explained in terms of an early vasodilatative effect, followed by a later onset of increased metabolic activity with high oxygen consumption.

5301 ADENYLATE CYCLASE AND PHOSPHODIESTERASE IN THE RAT GASTRIC MUCOSA AFTER STARVATION, FEEDING AND PENTAGASTRIN.

(E.) Ruoff, H. J.; Sewing, K. Fr. (Pharmacol. Inst., Univ. Tubingen, Germany). *Naunyn Schmiedebergs Arch. Pharmacol.* 288(2-3):147-153, 1975.

The effects of starvation, feeding, and pentagastrin on the gastric mucosal activities of adenylate cyclase and phosphodiesterase were studied in female Wistar rats. The rats were killed after 24- or 48-hr starvation which was, in some cases, followed by a period of refeeding, or after a single i.v. injection of pentagastrin (125 μg/kg). The mucosa from the fundus of the stomach was removed and homogenized and assayed for adenylate cyclase and phosphodiesterase. Starvation for 24 or 48 hr reduced both the basal and NaF-stimulated activities of adenylate cyclase without affecting the activity of phosphodiesterase. Refeeding of starved rats slowly raised the adenylate cyclase activity to up to 430% of basal values within 4 hr; this effect was more pronounced under basal conditions than with NaF stimulation. Pentagastrin caused a stimulation of basal adenylate cyclase lasting 45 min; this was followed by a subsequent decrease in the basal and NaF-stimulated enzyme activity. Phosphodiesterase activity was not influenced by refeeding but was transiently inhibited by pentagastrin. The results indicate that the gastric mucosal cyclic AMP levels after starvation, feeding, and pentagastrin are regulated by adenylate cyclase, not phosphodiesterase. The rise in adenylate cyclase activity after refeeding appears to be related to functions other than H^+ and pepsin secretion.

5302 EFFECTS OF ETHANOL ON GASTRIC ACID SECRETION AND GASTRIC MUCOSAL CYCLIC AMP IN THE RAT.

(E.) Puurunen, J.; Karppanen, H. (Dep. Pharmacol., Univ. Oulu, Finland). *Life Sci.* 16(10): 1513-1520, 1975.

The effect of ethanol on the secretion of gastric acid and on the content of cyclic AMP in the gastric mucosa was studied in male Sprague-Dawley rats. Ethanol was injected i.v. (10-800 mg/kg) or applied locally (1-10%) to the stomach for 5 or 25 min, after which gastric acid secretion was measured and the cyclic AMP content and activities of phosphodiesterase and adenyl cyclase in the glandular mucosa were determined. I.v. ethanol had no effect on the output of gastric acid, although there was a concentration-dependent decrease in acid secretion following local application. The latter effect was evident within 5 min; the rate of acid secretion decreased by about 30% with 1% ethanol and by 100% with 10% ethanol. Within 5 min of local application of 10% ethanol, the gastric mucosal content of cyclic AMP decreased by approximately 50%. A similar effect was observed *in vitro*; the decrease was about 30% with 2.5% ethanol, about 60% with 10% ethanol, and approximately 45% with 20% ethanol. In the presence of cyclic AMP (0.4-2μM), alcohol inhibited the activity of phosphodiesterase activity of the gastric mucosa in a competitive manner. The K_i-value was 0.16 M which would correspond to an alcohol concentration of 9.1%. In addition, ethanol caused a concentration-dependent inhibition of the activity of the gastric mucosal adenyl cyclase, the inhibition reaching nearly 100% with 0.166 M (9.4%) alcohol. It is concluded that the ethanol induced decrease of cyclic AMP in the gastric mucosa is due to a decreased formation of the nucleotide. The accompanying inhibition of acid secretion is consistent with the view that cyclic AMP is an intracellular regulator of gastric acid secretion. In view of the role of cyclic AMP in the control of cellular integrity, the ethanol-induced damage might also be at least partly due to the decreased mucosal concentration of cyclic AMP.

5303 PLASMA PROTEINS IN CANINE GASTRIC LYMPH.

(E.) Bruggeman, T. M. (Dep. Physiol., Univ. Michigan, Ann Arbor). *Gastroenterology* 68(5): 1204-1210, 1975.

A method for obtaining samples of gastric interstitial fluid *via* the collection of gastric lymph is described. Because it has not been possible to collect gastric lymph by the cannulation of lymph vessels, the methods of renal micropuncture were adapted to the collection and analysis of 0.5-3 μl samples obtained by puncturing lymph vessels on or immediately adjacent to the ventral surface of the dog's stomach. Samples of gastric lymph collected immediately after surgical exposure of the stomach were than subjected to acrylamide gel electrophoresis, and were found to show all the protein bands exhibited by simultaneously collected samples of plasma. Quantitative analysis of similar samples by cellulose acetate electrophoresis gave the following ratios of plasma:protein concentration in the gastric lymph: total protein, 0.51; albumin, 0.68; total globulins, 0.42; α_1-globulin, 0.49; α_2-globulin, 0.62; β-globulin, 0.35; fibrinogen, 0.39; and γ-globulin, 0.46. When samples were collected over 4-hr periods, the concentrations of all proteins in the lymph increased, a phenomenon which did not appear to be the result of increasing small pore size as the result of injury. When the mucosa was irrigated with solutions of dithiothreitol, a substance causing plasma shedding, the concentrations of proteins in the gastric lymph over a 4-hr period were similar to those found in control experiments. Gastric lymph mixed with 100 mN HCl was found to have proteolytic activity. The results suggest that albumin can leave gastric capillaries by restricted diffusion through small pores as well as by unrestricted diffusion through large pores.

5304 CHRONIC ALCOHOLISM AND ENDOGENOUS GASTRIN.

(E.) Treffot, M. J.; Tiscornia, O. M.; Palasciano, G.; Hage, G.; Sarles, H. (Unit Res. Dig. Pathol., Marseille, France). *Am. J. Gastroenterol.* 63(1):29-32, 1975.

The effects of a meat meal with or without ethanol infusion on serum gastrin levels were studied in dogs chronically treated with ethanol. Six of 10 dogs with chronic pancreatic and gastric fistulas were given 50% ethanol (2.0 mg/kg) daily for 1 yr; the remaining animals were given no alcohol (controls). After an 18-hr fast, the dogs were fed 150 g of raw meat alone or in association with 50% ethanol. Blood samples were collected 5, 15, 30, 45, 60, 90, and 120 min later. After the meat meal alone, the gastrin blood levels increased more quickly and remained elevated longer in the dogs chronically treated with ethanol than in the control dogs; this difference reached a peak of 40% after 90 min. The gastrin blood values were also higher in the ethanol-treated dogs following the ingestion of meat with concomitant infusion of ethanol; this difference reached a maximum of 86% after 30 min. The percentage increase in serum gastrin in the nonalcoholic dogs was greater and longer lasting following the ingestion of meat alone. The results suggest that ethanol is effective in releasing gastrin from the antrum. They also suggest that chronic ethanol intoxication increases the storage of gastrin in and its release from the antrum, a phenomenon which would explain the increased parietal cell mass and gastric acid secretion shown by animals subjected to chronic alcohol intoxication.

5305 EFFECT OF VAGAL INNERVATION ON THE SECRETORY RESPONSES OF CANINE GASTRIC POUCHES EXPOSED TO BILE.

(E.) Aubrey, D. A.; Burns, G. P. (Dep. Surg., State Univ. New York, Buffalo). *Am. J. Surg.* 129(5):518-522, 1975.

The secretory changes resulting from exposure of vagally innervated and vagally denervated canine fundic pouches to ox bile prior to a meat meal were studied. Male and female mongrel dogs were prepared with standard vagally denervated (Heidenhain) pouches or with similar pouches in which the anterior vagus nerve was preserved intact. Basal gastric secretions were measured in the fasted animals, after which a standard meat meal was administered and the gastric juice was collected in 15-min samples for 4 hr. In subsequent tests, the secretory responses of the pouches were assessed after preliminary exposure (30 min) to ox bile at pH 7 and pH 2. In the denervated pouches, the secretion patterns were similar after the meat meal alone (control) and after exposure of the pouches to bile at pH 7; however, the output of Na^+ was consistently higher in the pouches exposed to bile at pH 7 than in the control pouches. In the denervated pouches exposed to bile at pH 2, the output values for H^+, Cl^-, and K^+ were significantly lower than control values, while the output of Na^+ was significantly higher. The output of Na^+ and H^+ in the pouches exposed to bile at pH 2 was also significantly different from the output in the pouches exposed to bile at pH 7. The secretory volumes did not differ among the three groups. In the innervated pouches, the output of H^+ after exposure to bile at pH 7 was significantly reduced below control values and the output of Na^+ was significantly increased; these changes were more marked in the innervated pouches than in the denervated pouches. After exposure to bile at pH 2, the output of H^+ was more reduced in the secretions from the innervated pouches than in those from the denervated pouches, while the increase in Na^+ output was greater in the innervated pouches. The results suggest that the innervated mucosa is more susceptible than the denervated mucosa to the injurious effects of bile.

5306 EFFECT OF GASTRIC ALKALINIZATION ON LOWER ESOPHAGEAL SPHINCTER PRESSURE AND SERUM GASTRIN.

(E.) Kline, M. M.; McCallum, R. W.; Curry, N.; Sturdevant, R. A. L. (Veteran's Admin. Wadsworth Hosp. Cent., Los Angeles, Calif.). *Gastroenterology* 68(5):1137-1139, 1975.

The effect of alkaline intragastric pH on the lower esophageal sphincter pressure (LESP) and on the serum gastrin concentration was measured in eight men without esophageal disease. After an overnight fast, four-lumen polyvinyl tube assemblies with four lateral orifices were fitted into the subjects. A 0.1 N $NaHCO_3$ solution (110 ml) or a control solution was administered *via* gastric instillation and the LESP and intragastric pH were measured both before and after administration. The serum gastrin concentration was also measured before and at 5, 10, and 20 min after administration. The mean basal LESP was 16.7 mm Hg and the mean basal gastrin concentration was 21.6 fM/ml. Both parameters increased during administration of the solutions, but these increases were not significant; nor were there any significant differences between the LESP and serum gastrin measurements during instillation of the alkaline and control solutions. The gastric pH was greater than 7.0 during administration of the $NaHCO_3$ solution and between 2.0 and 6.9 during most of the control periods. It is concluded that intragastric alkalinization does not increase total radioimmunoassayable serum gastrin or LESP in man.

5307 INTERACTION OF CALCIUM AND MAGNESIUM ON GASTRIC ACID SECRETION AND SERUM GASTRIN CONCENTRATION IN MAN.

(E.) Christiansen, J.; Rehfeld, J. F.; Stadil, F. (Bispebjerg Hosp., Copenhagen, Denmark). *Gastroenterology* 68(5):1140-1143, 1975.

The effect of magnesium on calcium- and pentagastrin-induced gastric acid secretion and on calcium-induced gastrin secretion were studied in healthy male and female volunteers. Levin tubes were placed in the subjects' stomachs and saline was administered i.v. for a control period of 1 hr. Calcium gluconate (30 ml/hr) or pentagastrin (0.5 µg/kg-hr) was infused i.v. over the next 3 hr; i.v. infusion of magnesium sulfate (30 mg/hr) was begun after 2 hr. Calcium gluconate increased the serum gastrin concentration as well as the gastric volume secretion, acidity, and acid output. The addition of magnesium sulfate to the infusate caused a slight but insignificant increase in serum gastrin concentration, whereas volume secretion, acidity, and acid output were significantly depressed. Magnesium sulfate had no effect on the gastric acid secretion induced by a submaximal pentagastrin infusion. These results indicate that magnesium antagonizes the activation of gastric acid secretion by calcium without suppressing gastrin release and may suggest that magnesium does not change the sensitivity of the parietal cell to gastrin.

5308 ACTION OF THE ANTI-INFLAMMATORY AGENTS, ACETYLSALICYLIC ACID, INDOMETHACIN AND FENOPROFEN ON THE GASTRIC MUCOSA OF DOGS.

(E.) Lin, T. M.; Warrick, M. W.; Evans, D. C.; Nash, J. F. (Lilly Res. Lab., Eli Lilly Co., Indianapolis, Ind.). *Res. Commun. Chem. Pathol. Pharmacol.* 11(1):1-14, 1975.

The effects of acetylsalicylic acid (ASA), indomethacin, and fenoprofen on the integrity of the gastric mucosal barriers were measured by ionic fluxes into the gut lumen of three dogs with Heidenhain pouches. HCl (0.1 N, 30 ml) was infused into the pouches and removed at 30-min intervals for 6 hr. During the third and fourth periods, the acid instillate contained 4.5 mg/ml or 12.5 mM of ASA, indomethacin, or fenoprofen. All three agents affected the functional integrity of the mucosal barrier, but the characteristics of their actions differed. The H^+ concentration was decreased by ASA and fenoprofen and was increased by indomethacin, while all three drugs increased the net flux of Na^+, K^+, Ca^{++}, and Mg^{++}. Following initial augmentation of the instillate volume and H^+ concentration, indomethacin caused sustained back diffusion of acid from the lumen to the mucosa; this was accompanied by mucosal bleeding. The peak effects of ASA on the net ionic flux occurred during or immediately after drug infusion and were greater than those of indomethacin and fenoprofen. Fenoprofen at 12.5 mM had no effect on the concentrations of Ca^{++} or Mg^{++}, whereas both were significantly increased by equal molar doses of ASA or indomethacin. In onset of action, indomethacin was slow, but once disruption of functional integrity started, it continued for hours, showing no signs of returning to normal. In this sense, the total disruptive action of an equal weight or molar dose of indomethacin was greater than that of ASA or fenoprofen. At pH 1, the absorption of ASA from the Heidenhain pouch was greater than that of indomethacin or fenoprofen, their respective peak concentrations in the plasma being 53.9, 14.2, and 13.7 µM. The results suggest that fenoprofen may be less irritating and less ulcerogenic than ASA and indomethacin in the acid secreting stomach when the drugs are taken orally.

5309 EFFECT OF THE H_2-RECEPTOR ANTAGONISTS (BURIMAMIDE AND METIAMIDE) ON GASTRIC SECRETION STIMULATED BY HISTAMINE AND ITS METHYL DERIVATIVES.

(E.) Preiss, D. U.; Code, C. F. (Mayo Clin., Rochester, Minn.). *J. Pharmacol. Exp. Ther.* 193(2):614-620, 1975.

The comparative effectiveness of burimamide and metiamide as antagonists of gastric secretion stimulated by histamine and its methyl derivatives, N^{α}-methylhistamine, N^{α},N^{α}-dimethylhistamine and 4-methylhistamine, was studied in dogs with vagally denervated (Heidenhain pouches) and vagally innervated gastric mucosal septal pouches (Pavlov pouches). The secretagogues were given by continuous i.v. infusion to produce steady states of secretory activity in the fasted conscious dogs; the antagonists were given by either rapid bolus i.v. injection or continuous i.v. infusion. With bolus injections, both antagonists promptly inhibited the secretion produced by histamine and its methyl derivatives. At similar control secretory rates, 40 µM/kg burimamide and 4 µM/kg metiamide produced the same degree of inhibition. When the antagonists were given by continuous i.v. infusion, the difference between them was greater, metiamide being 15-17 times more potent than buriamamide. The effectiveness of the antagonists was not changed by vagal denervation. Symptoms of toxicity to burimamide developed at doses in excess of 30 µM/kg/hr; none occurred with metiamide at 1.8-7.5 µM/kg/hr. In addition to establishing the greater potency of metiamide, the continuous i.v. infusion experiments revealed differences in the action of histamine and N^{α}-methylhistamine. With histamine providing the background secretion, the dose of buriamamide necessary to produce 50% inhibition was 14.7 times greater than that of metiamide; when N^{α}-methylhistamine was the agonist, the multiple was 16.7. The results suggest a stronger binding by N^{α}-methylhistamine than by histamine to the H_2-receptor and supports the contention that histamine and N^{α}-methylhistamine have different affinities for the H_2-receptor of the parietal cell.

5310 TOPICAL CALCIUM AND pH EFFECT ON GASTRIN RELEASE AND PARIETAL CELL SECRETION. *(E.)* McLaughlin, M. H.; Peskin, G. W.; Greenburg, A. G.; Saik, R. P. (Univ. Calif. Sch. Med., San Diego). *J. Surg. Res.* 18(4):427-430, 1975.

The effects of topical Ca^{++} and the pH effects of its delivery vehicle on antral gastrin release and parietal cell secretion were studied using the following solutions: CaCl$_2$ (pH 2 and pH 8, 300 mOsm); NaCl (pH 2 and pH 8, 300 mOsm). Integrated gastrin output and total acid output were calculated for each 45-min test period in the 36 cats studied. Both the fundus and the antrum were perfused with the test solutions to differentiate the effects of Ca^{++} and the pH changes on the system. Antral perfusion failed to consistently alter gastrin output regardless of pH or ion involved. No significant increase in acid production was noted after either Ca or alkaline stimulation of the antrum. Topical perfusion of the fundus with alkaline solutions caused increased acid secretion without elevated gastrin output, and Ca produced a significantly greater acid response than Na. It is suggested that direct topical and reflex effects on the parietal cell may play an important role in gastric acid secretion stimulated by ingestion of food and may be more significant than small physiologic changes in serum gastrin levels.

5311 EFFECT OF ATROPINE IN REDUCING PLASMA PROTEIN SHEDDING BY THE CANINE OXYNTIC GLANDULAR MUCOSA INDUCED BY TOPICAL IRRIGATION WITH HISTAMINE OR COBRA VENOM. *(E.)* Kauffman, Jr., G. L.; Davenport, H. W. (Dep. Physiol., Univ. Michigan, Ann Arbor). *Gastroenterology* 69(1):198-199, 1975.

The mucosa of a vagally denervated (Heidenhain) pouch of the oxyntic glandular area of the stomachs in two dogs was irrigated for 30 min with dodecyl sulfate (20 mM solution in 15 mM phosphate buffer, pH 7.4) to break the gastric mucosal barrier. The mucosa was then irrigated for 30 min with histamine (1 mg/ml) solution. The experiment was repeated six times, during three of which the dogs were given i.v. atropine (0.0125 mg/kg) 15 min before the histamine solution was applied. Plasma shedding was very much lowered when histamine irrigation was preceded by atropine administration. A vagally denervated pouch of another dog was irrigated once weekly with a solution of lyophilized venom of *Naja naja* (0.5 mg/ml in phosphate buffer, pH 7.4). At the fourth week the characteristic response to the venom occurred. For 8 weeks thereafter, irrigation with venom preceded by i.v. injection of atropine (0.1 mg/kg) was alternated with irrigation without atropine. Atropine greatly reduced, but did not abolish, plasma shedding induced by venom irrigation. Plasma shedding induced by topical irrigation with 30% v/v ethanol in phosphate buffer, pH 7.4, was not affected by i.v. atropine (0.0125 mg/kg). These data allow the conclusion that plasma shedding exhibits a cholinergic component.

5312 EFFECT OF THE ANTRUM AND VAGUS NERVE ON BETAZOLE STIMULATION OF THE RAT STOMACH IN PERFUSION EXPERIMENTS. *(Ger.)* Hantschmann, N. (Surg. Clin., Univ. Kiel, Germany). *Arzneim. Forsch.* 25(2):216-222, 1975.

In perfusion tests the effect of a single injection of betazole (50 mg/kg s.c.) was studied in fasting male Wistar rats which had undergone bilateral truncal vagotomy, vagotomy and pyloroplasty, or antrectomy. Unoperated rats served as controls, and the completeness of vagotomy was tested with insulin in all cases. When vagotomy was performed immediately before the perfusion test, no change occurred in the betazole-induced increase in gastric acid secretion. However, when vagotomy was performed at least four weeks before the perfusion test, betazole produced a very slow increase in acid secretion. Maximum values, attained 4 hr after injection, were half those obtained in unoperated controls and rats subjected to vagotomy immediately before the perfusion test. All but three of the 16 rats in this group had gastric dilatation and, despite a 24-hr fast, large quantities of food, hair, and dirt in their stomachs. Dilatation persisted, even after thorough rinsing of the stomach. To rule out the possibility that gastric dilatation affects acid secretion, truncal vagotomy was combined with pyloroplasty in 22 rats. Four or more weeks after surgery, betazole caused an increase in acid secretion which was just significantly above basal values within the first two hr after injection. Acid secretion then decreased, and basal values were reached 1 hr later. In 21 rats which had undergone antrectomy at least 4 weeks before the test, betazole produced a significant increase in acid secretion only 3 hr after injection, with maximum values being reached after 4 hr. When curves for rats subjected to vagotomy and pyloroplasty and those subjected to antrectomy alone were added, the resulting curves corresponded to those obtained on unoperated controls or on recently vagotomized animals during the first 3.5 hr of the perfusion test. These results suggest that betazole acts directly on the parietal cells and also produces cholinergic stimulation *via* the vagus nerve.

5337 ANALYSIS OF THE MECHANISM OF ACTION OF CALCIUM-INDUCED EXOCRINE PANCREATIC SECRETORY CHANGES IN THE DOG. *(E.)* Tiscornia, O.; Palasciano, G.; Dzieniszewski, J.; Verine, H.; Sarles, H. (Unit Res. Dig. Dis., Marseille, France). *Am. J. Gastroenterol.* 63(4):293-298, 1975.

To elucidate the role of the cholinergic system in the calcium-induced exocrine pancreatic secretory changes in the dog, an i.v. calcium infusion was superimposed on a continuous perfusion of secretin in dogs with and without an atropine-induced cholinergic blockade. GIH secretin (1 CU/kg/hr) was infused i.v. into mongrel dogs with gastric and duodenal fistulas (Thomas cannula); after 80 min, a second i.v. infusion of calcium (10 mg/kg) was begun and was continued for 60 min. In a second experiment, i.v. atropine infusion (1.5 mg/hr) was begun 80 min after the beginning of secretin infusion and calcium infusion was commenced 60 min later. In the absence of atropine-induced cholinergic blockade, i.v. calcium increased the flow rate, bicarbonate concentration and output, and protein concentration and output of the pancreatic juice; the greatest effects were on the protein concentration (increased by 148%) and output (increased by 173%). During atropine-induced blockade, i.v. calcium changed neither the flow rate nor the bicarbonate output of the secretin-induced pancreatic juice. On the other hand, i.v. calcium increased the protein concentration and output by 85% and 40%, resp., under these conditions. The results suggest that i.v. calcium enhances secretin-induced pancreatic secretion plateau values *via* two mechanisms: primarily by raising the cholinergic tone of the whole "pancreon"; and partially through a direct stimulus-secretion coupling effect on the acinar cells.

5338 MICROFILAMENTOUS SYSTEM AND SECRETION OF ENZYME IN THE EXOCRINE PANCREAS: EFFECT OF CYTOCHALASIN B. *(E.)* Bauduin, H.; Stock, C.; Vincent, D.; Grenier, J. F. (Fac. Med., Free Univ. Brussels, Belgium). *J. Cell Biol.* 66(1):165-181, 1975.

The influence of cytochalasin B (CB) on the exocrine function of the pancreas was studied *in vitro* using pieces of fasted adult rat pancreas. The pieces of pancreas were incubated in medium containing an L-amino acid mixture, D-glucose, buffer, and CB in ethanol solution. Parameters studied included the conversion of glucose into proteins and CO_2, the incorporation of glucose in the pancreatic pieces, sugar transport, the conversion of 2-deoxy-D-glucose to 2-deoxy-D-glucose-6-phosphate, calcium uptake, and the efflux of calcium. The pancreatic fragments were also studied by electron microscopy. The results showed that the microfilaments in the acinar cell are essentially located in the apical portion of the cell. Thin CB-sensitive microfilaments (50 Å) form the axis of the microvilli and a network lying beneath the apical membrane, while thicker filaments (100 Å), which are at least partly CB-insensitive, form bundles parallel to the plasma cell membrane and the desmosomal links. CB interaction with the aci cell of the exocrine pancreas involves at least tw sites: a membrane site involved in the inhibitory effect of CB on monosaccharide transport and a les sensitive site at the filamentous level which is a least partially responsible for the inhibitory eff of CB on the secretion of exportable enzyme from t pancreatic cell. CB did not alter the energy bala of the acinar cell or the exchanges of ^{45}Ca betwee the extracellular medium and the pancreatic tissue CB at 2 x 10^{-7} and 2 x 10^{-6} M had secretagogue pro erties, whereas at 2 x 10^{-5} M, it had an inhibitor effect on stimulated secretion and secretagogue pr erties. The mechanism of these secretory effects unknown. The data provide strong evidence for the involvement of the microfilamentous network in the last steps of the secretory cycle in the acinar ce of the exocrine pancreas.

5339 INCREASED PARATHYROID HORMONE SECRETION HYPOCALCEMIA IN EXPERIMENTAL PANCREATITI NECESSITY FOR AN INTACT THYROID GLAND. *(E.)* Norb H. P.; DeRoos, J.; Kaplan, E. L. (Univ. Chicago, Pritzker Sch. Med., Ill.). *Surgery* 77(6):773-779, 1975.

The role of the parathyroid and thyroid glands in the production of the hypocalcemia accompanying ac pancreatitis was studied in pigs. Acute pancreati was induced in thyroidectomized animals and in pig with intact thyroids; sham-operated pigs served as controls. Before and at various intervals for 48 after the induction of pancreatitis, arterial bloo samples were analyzed for blood urea nitrogen (BUN serum electrolytes, total protein, amylase, total cium, magnesium, phosphorus, and serum parathyroid hormone (PTH). The basal values for these paramet did not vary between normal, sham-operated, and th roidectomized pigs. After induction of pancreatit in the thyroid-intact pigs, however, serum amylase increased to more than 350% of the basal value, ar serum calcium concentrations significantly increas between 8-24 hr, thereafter returning to normal. Serum PTH concentrations also increased significar between 8-18 hr following the induction of pancrea titis, the peak PTH concentration (167% above basa values) occurring at 12 hr. Although serum amylas values also increased in the thyroidectomized pigs after the induction of pancreatitis, serum calcium and PTH did not vary from basal values. In all ar mals with acute pancreatitis, the serum magnesium, phosphorus, total proteins, BUN, and electrolytes mained within basal limits. The data support the view that calcitonin or another thyroid-related su stance plays a role in the mechanism of the hypoca cemia which accompanies experimental pancreatitis the pig.

5340 ACUTE HEMORRHAGIC PANCREATITIS (MASSIVE NECROSIS) WITH FAT NECROSIS INDUCED IN MICE BY DL-ETHIONINE FED WITH A CHOLINE-DEFICIENT DIET. *(E.)* Lombardi, B.; Estes, L. W.; Longneck D. S. (Univ. Pittsburgh Sch. Med., Pa.). *Am. J. Pathol.* 79(3):465-480, 1975.

The anatomicropathologic and ultrastructural alterations observed in the pancreatic tissues of mice fed DL-ethionine with a choline-deficient diet are described. Thirty-day-old female Swiss Webster mice were placed on choline-deficient diets (controls) or choline-deficient diets in which 0.5% DL-ethionine replaced an equal amount of sucrose (experimental animals). All experimental mice died within 5 days due to the development of an acute hemorrhagic pancreatitis with fat necrosis throughout the peritoneal cavity; none of the controls died within this time interval. The pancreatitis in the experimental animals was characterized by a massive necrosis of the exocrine parenchyma with intense hemorrhage and inflammatory reaction of the stroma. The sequence of histologic and ultrastructural alterations occurring in the acinar cells of the pancreas was studied in the controls and in mice fed the experimental diet for 1, 2, or 3 days. Pancreatic tissues of control mice were histologically normal. In those of mice fed the experimental diet for 1 day, acinar cells were intensely eosinophilic, and there were numerous zymogen granules and a considerable reduction in the amount of basal and perinuclear basophilia. After 2 days, the loss of basophilia was almost complete; there were numerous, small, cytoplasmic vacuoles, primarily in the basal portions of the cells; and the pancreatic stroma showed a moderate degree of edema and congestion. The vacuolation of the acinar cells became more extensive after 3 days and cellular necrosis was evident; the interstitial edema and congestion were more severe. The pancreatitis in the experimental mice appeared to be due to intraparenchymal activation of zymogens, resulting from a synergistic action of choline deficiency with the basic toxicity of ethionine toward pancreatic acinar cells. This experimental model closely simulates the acute hemorrhagic pancreatitis with fat necrosis occurring in humans and may prove useful for exploring the pathogenesis of this condition.

5341 FACTORS INVOLVED IN THE INTESTINAL FEEDBACK REGULATION OF PANCREATIC ENZYME SECRETION IN THE RAT. *(E.)* Schneeman, B. O.; Lyman, R. L. (Dep. Nutr. Sci., Univ. California, Berkeley). *Proc. Soc. Exp. Biol. Med.* 148(3):897-903, 1975.

The mechanisms involved in the intestinal stimulation of pancreatic secretion were studied using male Wistar rats, prepared with bile-pancreatic or pancreatic and intestinal cannulas. Lyophilized soybean trypsin inhibitor (SBTI), trypsin, diisopropyl fluorophosphate (DFP)-treated trypsin, chymotrypsin, or DFP-chymotrypsin was infused into the intestine; in other experiments, pancreozymin, trypsin, SBTI, chymotrypsinogen, or cholecystokinin (CCK) was infused into the jugular vein. The bile-pancreatic juice was collected during the infusion studies and was analyzed for total protein and chymotrypsin using the synthetic substrate *n*-benzoyl-L-tyrosine ethyl ester. SBTI stimulated pancreatic enzyme secretion only when introduced into the upper third of the small intestine. In rats whose pancreatic juice had previously been diverted for 10 hr, both trypsin and chymotrypsin suppressed the pancreatic protein output in a dose-dependent fashion, maximal suppression being obtained with 10 mg of trypsin/0.5 hr. DFP-trypsin and DFP-chymotrypsin had no such effect. The inhibitory effect of trypsin occurred only when the enzyme was infused into the upper third of the intestine. Trypsin, chymotrypsinogen, and SBTI had no significant effect on the pancreatic output when infused directly into the jugular vein. CCK infusion significantly increased the pancreatic enzyme output in rats whose pancreatic juice had been continually returned to the intestine; this increase was much smaller when the juice had been diverted for the preceding 10 hr. The results suggest that trypsin in the upper small intestine somehow prevents the release of CCK into the blood and that SBTI releases CCK by binding the trypsin and removing it from the intestine. Trypsin and chymotrypsin appear to exert their feedback regulation of pancreatic secretion in intestine.

5342 ENTEROPANCREATIC CIRCULATION OF DIGESTIVE ENZYMES. *(E.)* Liebow, C.; Rothman, S. S. (Cornell Univ. Med. Coll., New York, N. Y.). *Science* 189(4201):472-474, 1975.

The possible existence of a cycle involving the absorption of intact digestive enzymes by the intestine and their resecretion by the pancreas was investigated. Whole rabbit pancreases were excised and placed in an organ both containing bovine (^{3}H)chymotrypsinogen and human (^{131}I)albumin. The pancreatic duct was cannulated and the secretion was collected directly. The chymotrypsinogen concentrations in the secretion continued to rise for 1 to 2 hr before a steady-state secretory concentration was reached; about 3% of the chymotrypsinogen was of exogenous origin. The transpancreatic movement of this enzyme appeared to occur at least in part *via* an intracellular route. In another experiment, cholecystokinin-pancreozymin was added to the organ bath after (^{3}H)-labeled rabbit amylase (previously added) had achieved a steady-state concentration in the pancreatic secretion. After the addition of the hormone, the concentration of (^{3}H)amylase in the secretion rose markedly. In a further set of experiments, the mucosal to serosal flux of (^{3}H)chymotrypsinogen relative to that for (^{131}I)albumin was compared in gut sacs prepared from rabbit ileum. The permeability of the ileal membrane to chymotrypsinogen expressed per unit of concentration gradient was about 9-fold greater than that for albumin. Finally, to directly examine the circulation of enzyme, (^{3}H)chymotrypsinogen was placed in the intestine just down-stream from the intestinal opening of the pancreatic duct and the pancreatic secretion was collected from the cannulated duct. The ^{3}H chymotrypsinogen peaked in the secretion within 15 min; about 67% of the secreted label comigrated with bovine chymotrypsinogen under disc gel electrophoresis. The results indicate the existence of an enteropancreatic circulation for at least some digestive enzymes, although the magnitude of this process remains uncertain. In addition, the fluxes observed across the pancreas and intestine were of sufficient magnitude to indicate the possibility of a conservation mechanism.

5343 EFFECT OF OXYTETRACYCLINE AND CHLORAMPHENICOL ON THE EXOCRINE PANCREATIC FUNCTION IN THE RAT. *(E.)* Fleischer, K. (Med. Clin. Univ. Wurzburg, Germany). *Digestion* 11(5-6):382-391, 1974.

The effects of oxytetracycline and chloramphenicol pretreatment on pancreatic secretion under exogenous stimulation were studied in specific pathogen-free male rats of the Chbb: THOM strain. The animals were provided with bile-pancreatic cannulas and 12 days later were treated with oxytetracycline (20 mg/kg/hr, i.v. beginning 1 hr before the collection of pancreatic secretion, or 200 or 400 mg/kg/day, s.c. for 3 days prior to the collection of pancreatic secretion) or chloramphenicol (0.6 g/kg in 4% Tylose solution by stomach tube 12 hr before the collection of pancreatic secretion, or 0.6 or 1.2 g/kg/day for 3 days prior to the collection of pancreatic secretion). The serum antibiotic levels were determined in some animals. In others, pancreatic secretion was stimulated by the continuous i.v. infusion of 25 U/kg/hr of secretin and 25 U/kg/hr of pancreozymin. The protein and electrolyte concentrations and activities of amylase, trypsin, and lipase in the pancreatic secretion were measured. Short-term pretreatment with oxytetracycline or chloramphenicol produced no significant changes in the exogenously stimulated pancreatic secretion. However, after 3 days of pretreatment with either antibiotic, an approximately dose-dependent decrease in the exogenously stimulated pancreatic secretion was observed; this decrease was reflected in both the protein output and in the enzyme activities of the secretion. The volume and electrolyte output of the pancreatic secretion remained essentially unchanged. Immediately following the cessation of long-term antibiotic treatment, the serum oxytetracycline levels decreased steadily, while the serum levels of chloramphenicol decreased initially, and then remained relatively constant between 6 and 15 hr after treatment. Since short-term antibiotic treatment produced no changes in pancreatic secretion, the observed alteration after longer-term treatment appears to be largely attributable to a depression of enzyme protein synthesis.

5344 BIOCHEMICAL GENETICS OF α-AMYLASE ISOZYMES OF THE CHICKEN PANCREAS. *(E.)* Lehrner, L. M.; Malacinski, G. M. (Dep. Zool., Indiana Univ., Bloomington). *Biochem. Genet.* 13(1/2):145-173, 1975.

α-Amylase isozyme patterns and patterns of inheritance were studied in pancreatic tissue from phenotypically different chickens. In the chicken population at large, three electrophoretically distinct pancreatic α-amylase isozymes were discovered. The isozymes were designated Pa 1, Pa 2 and Pa 3. The local population of chickens, however, possessed only isozymes Pa 2 and Pa 3 (present as three phenotypes: Amy_2 B, consisting of isozyme Pa 2, Amy_2 BC, consisting of isozymes Pa 2 plus Pa 3 and Amy_2 C, consisting of isozyme Pa 3). Pancreatic biopsy permitted the establishment of a breeding flock with defined amylase phenotypes. Matings of this flock established that amylases are inherited as codominant alleles at a single genetic locus. Further, there was no evidence of ontogenetic modification of the amylase isozymes. It was observed that amylase isozymes Pa 2 and Pa 3 each generated a family of at least three faster-migrating amylolytic proteins. These post-translationally-modifed amylases were designated Pa Xa, Pa Xb, and Pa Xc, where X represents the number of the progenitor amylase. Structural analyses of purified amylases demonstrated that all amylase isozymes are nonglycosidated, monomeric molecules of molecular weight 55,000. In addition, the data are consistent with the hypothesis that the faster-migrating amylases are produced by deamination of asparagine and/or glutamine residues.

SECRETION AND METABOLISM

Hepatobiliary Tract

5353 BILE ACIDS SECRETION AND SYNTHESIS BY ISOLATED RAT HEPATOCYTES. *(E.)* Anwer, M. S.; Kroker, R.; Hegner, D. (Inst. Pharmacol., Toxicol. Pharm., Univ. Munich, Germany). *Biochem. Biophys. Res. Commun.* 64(2):603-609, 1975.

The synthesis and secretion of bile acids by isolated rat hepatocytes were studied. Hepatocytes were isolated from the livers of male Wistar rats and incubated in cell suspension. The supernatants were assayed for bile acids, lactate, pyruvate, and glucose and the results were compared with those obtained with bile samples collected *in vivo*. Bile acid secretion *in vitro* was linearly related to time for the first 3 hr of incubation; the net secretion rate was 23.2 mM/g of cells/min. The biliary excretion rate of bile acids by male Wistar rats has been reported to be 51.8 mM/g liver/min. The distribution of individual bile acids in the incubation media was significantly different from that in the *in vivo* bile samples. The ratio of taurine to glycine conjugates was significantly higher in the bile than in the incubation media; the ratio of dihydroxy to trihydroxy bile acids was significantly higher in the incubation media, and the ratio of chenodeoxycholic acid to cholic acid was higher in the incubation media than in the bile samples. The results indicate that isolated rat hepatocytes would provide a suitable experimental system for studying the effects of drugs and hepatic diseases on bile acid secretion and synthesis at the cellular level. The relatively higher synthesis of chenodeoxycholic acid in the hepatocytes could be used to study the mechanism controlling the relative proportion of primary bile acid synthesis from cholesterol.

5354 ANALYSIS OF REGULATORY FACTORS FOR UREA SYNTHESIS BY ISOLATED PERFUSED RAT LIVER. II. COMPARISON OF UREA SYNTHESIS IN LIVERS OF RATS SUBJECTED TO DIFFERENT DIETARY CONDITIONS. *(E.)* Saheki, T.; Tsuda, M.; Tanaka, T.; Katunuma, N. (Sch. Med., Tokushima Univ., Japan). *J. Biochem. (Tokyo)* 77(3):671-678, 1975.

The effects of dietary protein on urea synthesis and amino acid patterns in isolated, perfused rat liver were studied. Adult male Wistar rats were maintained for 4-24 days on 5% or 70% casein diets, after which their livers were perfused with medium with ammonium chloride as the nitrogen source. Urea formation in the livers of the rats fed the 70% casein diet was rapid and the efficiency of conversion of ammonia to urea was 97.9%. In contrast, urea formation in the livers of the rats fed the 5% casein diet was much slower and the efficiency of conversion of ammonia to urea was only 36.1%. In addition, the ratio of the rate of urea formation from ammonium chloride to the activity of ornithine transcarbamylase was much lower in the rats fed the low-protein diet than in those fed the high-protein diet. The addition of ornithine and *N*-acetylglutamate to the perfusate caused marked elevations in these ratios, two of which reached nearly the same level in both groups of rats. In the perfused livers from rats fed the 5% casein diet, a large portion of the ammonia added to the perfusate was fixed into an amino or an amide group of amino acids such as alanine, aspartate, and glutamine. In the perfused livers from the rats fed the 70% casein diet, most of the added ammonia was converted to urea. The results suggest that factors other than the amounts of urea cycle enzymes may play an important role in determining the flux through the urea cycle *in vivo*; these factors appear to be ornithine and *N*-acetylglutamate. The larger hepatic concentrations of nonessential amino acids in the rats fed the low protein diet may have resulted from the conversion of ammonia to nonessential amino acids; the fact that serine and glycine were not increased in the perfused livers suggests that their synthesis in the liver requires other factors or that they are converted rapidly into other compounds.

5355 METABOLISM OF RETINOL-BINDING PROTEIN AND VITAMIN A DURING HYPERVITAMINOSIS A IN THE RAT. *(E.)* Mallia, A. K.; Smith, J. E.; Goodman, D. S. (Columbia Univ. Coll. Physicians Surg., New York, N.Y.). *J. Lipid Res.* 16(3):180-188, 1975.

The effects of excess vitamin A on the plasma concentration and metabolism of retinol-binding protein (RBP) in the rat were studied. In the first experiment, weanling male Holtzman rats were given 0.14, 7.3, or 41 mg/day vitamin A, p.o., for 50-99 days. Plasma vitamin A and RBP levels were determined in samples obtained at various intervals between days 1 and 93. In the second study, adult Holtzman rats were given 0.14 or 34.4 mg retinal acetate daily for 23 days; these animals were also given daily p.o. doses of 0.67 μCi of ^{3}H-retinyl acetate. In both studies, administration of large, excessive doses of vitamin A resulted in substantial and significant decreases in the serum RBP levels. Excessive doses of vitamin A also produced fatty liver in association with a normal (in rats fed 7.3 mg vitamin A/day) or decreased (in rats fed 41 mg vitamin A/day) liver RBP concentration. In addition, the serum vitamin A levels were elevated in the animals fed excessive vitamin A, an effect which was due primarily to large increases in the circulating retinyl ester levels. In the hypervitaminotic rats, most of the serum vitamin A and virtually all of the retinyl esters were found in association with the serum lipoproteins of less than 1.21 hydrated density. The results indicate that the serum lipoproteins play an important role in the transport of the vitamin A which accumulates in the serum during excessive vitamin A intake. It is suggested that the toxic manifestations of hypervitaminosis A occur when vitamin A circulates in the plasma and is presented to the membranes in a form other than bound to RBP. Plasma lipoproteins may nonspecifically deliver vitamin A to biological membranes, thus leading to vitamin A toxicity.

5356 COBALT STIMULATION OF HEME DEGRADATION IN THE LIVER: DISSOCIATION OF MICROSOMAL OXIDATION OF HEME FROM CYTOCHROME P-450. *(E.)*

Maines, M. D.; Kappas, A. (Rockefeller Univ., New York, N.Y.). *J. Biol. Chem.* 250(11):4171-4177, 1975.

The relation of the cytochrome P-450 mixed function oxidase system to heme catabolism in liver cells was studied in rats. Male Sprague-Dawley rats were injected with cobalt chloride (60 mg/kg s.c.), cobalt protoporphyrin-IX or protoporphyrin-IX alone (4 μM/100 g i.p.), 3-amino-1,2,4-triazole (3 g/kg i.p.), or allylisopropylacetamide (400 mg/kg s.c.). In some cases, the animals also received i.p. injections of actinomycin D (0.06 mg/100 g or puromycin (2 mg/100 g). The rats were sacrificed after a 24-hr fast and liver microsomes analyzed for oxidative and δ-aminolevulinic acid synthetase activity. Cobalt chloride administration caused a marked increase in the oxidative degradation of heme (hematin, iron protoporphyrin-IX) beginning within 2 hr after cobalt treatment and reaching a maximum in 16-24 hr. During the rapid phase of stimulation, when heme oxidation was 450% above control values, there was a significant decrease in microsomal oxidative N-demethylation activity and in the microsomal heme content, with a nonsignificant decrease in the microsomal cytochrome P-450 concentration. Within 24 hr, the oxidative activity of the microsomal electron transport chain for drugs decreased to about 30% of control values and heme oxidation approached levels 800% above control. During this period there was a further decrease in the microsomal heme concentration, a significant decrease in cytochrome P-450, and an increase in the activity of δ-aminolevulinate synthetase. These parameters returned to normal within 72 hr. The effect of cobalt on heme oxidation could be inhibited by actinomycin D or puromycin administration; the effect could not be elicited by *in vitro* cobalt treatment of the microsomes nor attributed to any soluble cytoplasmic components. Cobalt protoporphyrin-IX was less effective than cobalt chloride in stimulating heme oxidation and protoporphyrin-IX alone had no effect. 3-Amino-1,2,4-triazole did not enhance hepatic heme oxidation while allylisopropylacetamide decreased it. The oxidative degradation of heme was not cytochrome P-450-dependent. The results exclude an obligatory role for cytochrome P-450 in the oxidation of heme compounds, although the possibility that this process is a heme-dependent oxidation is not ruled out.

5357 PREREPLICATIVE ENZYMIC CHANGES IN REGENERATING RAT LIVER. *(E.)*

Ebina, Y.; Iwai, H.; Fukui, N.; Ohtsuka, H.; Miura, Y. (Chiba Univ. Sch. Med., Japan). *J. Biochem. (Tokyo)* 77(3):641-645, 1975.

The sequential changes in the activities of ornithine decarboxylase and inosinic acid dehydrogenase in the early period of hepatic regeneration were studied in rats, as was the activation of thymidine kinase and the decrease in cyclic-AMP-phosphodiesterase activity during the later phases of the G_1 period. Male Sprague-Dawley and female Donryu rats were subjected to partial hepatectomy and samples of the regenerating liver were examined for the various enzyme activities and the intracellular cyclic AMP level. The activity or ornithine decarboxylase and inosinic acid dehydrogenase increased soon after partial (70%) hepatectomy, the former continuing to increase for about 10 hr and remaining fairly high for about 32 hr, and the latter reaching a maximum at 8-12 hr. Thymidine kinase activity increased about 24 hr after surgery, with the regeneration process somewhat more rapid in the Sprague-Dawley strain than in the Donryu strain. The intracellular cyclic AMP level showed a biphasic increase at 8 and 24 hr, while the activity of cyclic AMP phosphodiesterase showed no appreciable change during the first 16 hr then rapidly decreased from 16-18 hr. The low level of phosphodiesterase coincided with the period of the second steep rise in the cyclic AMP level. The results suggest that the increase in ornithine decarboxylase activity and the change in the intracellular level of cyclic AMP are important in the regulation of hepatic DNA replication. It is further suggested that inductions of inosinic acid dehydrogenase and thymidine kinase in the late prereplicative period in the regenerating liver is essential for DNA synthesis.

5358 THE KINETIC CHARACTERISTICS OF INHIBITION OF HEPATIC CHOLESTEROGENESIS BY LIPOPROTEINS OF INTESTINAL ORIGIN. *(E.)*

Nervi, F. O.; Weis, H. J.; Dietschy, J. M. (Univ. Texas Health Sci. Cent., Dallas). *J. Biol. Chem.* 250(11):4145-4151, 1975.

The kinetic characteristics of the uptake of cholesterol from intestinal lipoproteins by the rat liver were studied and this phenomenon was correlated with the inhibition of hepatic cholesterogenesis by the lipoproteins. Lipoprotein extracted from donor rats was injected i.v. into female Sprague-Dawley-derived rats as a single bolus or by means of an infusion pump at a rate of 0.2 ml/min; in some cases, rats were instead fed a diet containing 0, 0.1, 0.3, 0.8, or 1.2% cholesterol. The animals were killed after 48 hr, the livers removed and sliced, and the rates of cholesterol and total ketone synthesis determined. Net cholesterol uptake from the circulating intestinal lipoproteins took place only in the liver, and only this tissue manifested inhibition of cholesterol synthesis. Cholesterol uptake by the liver, quantified by a rise in the cholesterol ester content, was a linear function of time and of the amount of lipoprotein cholesterol administered to the animals. In all rats there was a general correlation between inhibition of the rate of cholesterol synthesis and the cholesterol ester content in the liver. However, there was no consistent quantitative relation between these two variables, suggesting either that cholesterol ester was not the immediate effector of the inhibition or, alternatively, that there was an intracellular localization of the effector at the site of control of the rate-limiting enzyme in the cholesterogenic pathway.

5359 ANALYSIS OF REGULATORY FACTORS FOR UREA SYNTHESIS BY ISOLATED PERFUSED RAT LIVER. I. UREA SYNTHESIS WITH AMMONIA AND GLUTAMINE AS NITROGEN SOURCES. *(E.)*

Saheki, T.; Katunuma, N. (Sch. Med., Tokushima Univ., Japan). *J. Biochem. (Tokyo)* 77(3):659-669, 1975.

Urea synthesis in isolated, perfused Wistar rat liver was studied using ammonium chloride and glutamine as nitrogen sources. Samples of the perfusate were taken at 5-20 min intervals and analyzed for urea formation from ammonia and glutamine and for the additional influences of urea cycle intermediates and cofactors. Concentrations of urea, ammonia, and various amino acids were also measured in a sample of liver taken at the end of the experiment. The rate of urea formation increased with ammonium chloride concentration up to 5 mM but remained constant at concentrations of 5-20 mM. The concentration of ammonia in the medium needed to support the half-maximum velocity of urea formation was 0.7 mM. Aspartate (10 mM) and ornithine (2.5 mM) stimulated the rate of urea formation with ammonia. The greater part of the added ornithine was accumulated as citrulline in the liver, indicating that arginosuccinate synthetase was the rate-limiting enzyme of the urea cycle in the perfused liver. N-acetylglutamate also stimulated urea synthesis, but high concentrations (20 mM) were required for the maximum effect. Ornithine and N-acetylglutamate had an additive effect on urea formation. Urea formation from 10 mM glutamine occurred in 3 stages: in the first lag phase, a small amount of glutamine was removed from the medium; in the second stage, the glutamine level decreased rapidly and ammonia was accumulated in the perfusate; and in the third stage the glutamine concentration remained at a constant low level while the accumulated ammonia was rapidly converted into urea. The rate of urea formation in the third stage was much higher than with ammonia as the substrate. Urea formation from glutamine was also stimulated by the addition of ornithine, malate, or N-acetylglutamate to the perfusate. This stimulation was due to an effective conversion of ammonia to urea, the rate of removal of glutamine being unchanged.

5360 TEMPERATURE SENSITIVITY OF BROMOSULPHOPHTHALEIN CLEARANCE BY THE LIVER. *(E.)*

Harris, P. J.; Noble, A. R.; Munday, K. A. (Dep. Physiol. Biochem., Med. Biol. Sci. Build., Southampton, England). *Experientia* 31(4):447-449, 1975.

The effect of temperature on BSP clearance by the isolated, perfused rat liver was studied. Livers from nonfasted male Wistar rats were perfused with a solution containing 10 mg BSP or 20 mM lactate and maintained at 37 C or 27 C. The bile duct was cannulated and the bile flow measured directly, and samples of the perfusate were analyzed at various intervals for BSP and lactate concentration. At 37 C, lactate was taken up from the perfusate at a mean rate of 0.84 μM/min/g, while at 27 C, the rate of lactate consumption was reduced by 45% to 0.46 μM/min/g. The mean rate of bile secretion was also reduced by 47% at 27 C (0.43 μliters/min/g) relative to 37 C (0.82 μliters/min/g). Changes in temperature had no effect on the structure of the liver cells. The initial mean rate of removal of BSP at 37 C was 21.7 μg/min/g, and at 27 C this was reduced to 7.4 μg/min/g; the percentage extraction of BSP at 37 C was 10.0%, while that at 27 C was 5.3%. In addition, while there was a linear disappearance of BSP from the perfusate at 27 C, the removal of BSP at 37 C was greater in the presence of high BSP concentrations than in the presence of low BSP concentrations in the perfusate. The correlation between the perfusate flow rate through the liver, as measured by application of the Fick principle to BSP clearance, and direct collation of the venous outflow was determined. The results indicate that under the conditions described, the mean hepatic blood flow rate can be calculated from BSP clearance at reduced temperatures.

5361 ALCOHOL SELECTION BY DBA AND C57BL MICE ARISING FROM OVA TRANSFERS. *(E.)*

Randall, C. L.; Lester, D. (Sch. Med., Univ. Florida, Gainesville). *Nature* 255(5504):147-148, 1975.

To determine the relative contributions of heredity and environment to alcohol selection by mice, preferences and aversions to alcohol were measured in mice arising from ova transfers between mothers of different strains. Ova donors and recipients were primiparous adult C57BL/6 (alcohol preferrers) and DBA/2 (alcohol avoiders) mice; transfers were made between mice of the same and different strains. The pups were weaned at 25 days and housed individually for 7 days; during this period they were offered a choice between tap water and 7.5% ethanol. The C57BL mice weighed more and drank more alcohol and less water than the DBA mice, and control mice of both strains (not subjected to ova transfer) drank less alcohol and more water than the transferred mice. Thus, the C57BL offspring arising from ova transplanted into DBA mothers not only retained but increased the strain-typical high alcohol preference. The offspring arising from DBA ova transferred to C57BL mothers, on the other hand, also increased their alcohol consumption and did not retain their strain-typical aversion to alcohol. The results support a genetic basis for alcohol selection in the

C57BL mouse, the nature of which remains unknown, while demonstrating that alcohol avoidance in DBA mice is subject to environmental manipulation.

5362 EFFECT OF CHOLERETICS ON BILIARY AND URINARY EXCRETION OF CHOLECYSTOGRAPHIC AGENTS.

(E.) Cooke, W. J.; Mudge, G. H. (Dartmouth Med. Sch., Hanover, N.H.). *Invest. Radiol.* 10(3):189-196, 1975.

The effects of the 2 choleretic agents, taurocholate and cinchophen, on the biliary and urinary excretion of 2 related cholecystographic agents, iopanoic acid and iophenoxic acid, were studied in adult mongrel dogs. The cystic duct was ligated and the common bile duct was cannulated in the anesthetized animals. Sodium iopanoate was infused at a constant rate of 1.6 ml/min in 2% mannitol in isotonic saline; iophenoxic acid was given in an initial dose of 4 mg/kg and sustaining infusions were not used. Sodium taurocholate was infused as a 1.3% solution in isotonic saline at 1.6 ml/min, and cinchophen was given in a priming dose of 50 mg/kg then infused in isotonic saline to provide 40 μg/kg/min. Urine was collected with an indwelling catheter, and liver biopsy samples were obtained during the experiment. The effect of each choleretic agent was specific for its related cholecystographic compound. Taurocholate increased both the biliary and urinary excretion of iopanoic acid and decreased its intrahepatic concentration, but had no effect on iophenoxic acid. Cinchophen had no effect on iopanoic acid but increased both the biliary and urinary excretion of iophenoxic acid. When examined against a preexisting high rate of bile flow, the active choleretic increased, rather than decreased, the biliary concentration of the respective cholecystographic compound. The increased excretion in both the bile and urine cannot be attributed simply to the reduced concentration gradient from plasma to bile, as has been previously suggested. The data are consistent with a direct action of the choleretic agent on hepatic mechanisms, either to decrease intracellular binding or to alter the characteristics of transport.

5363 OCTANOATE METABOLISM IN THE ISOLATED PERFUSED RAT LIVER. II. COMPARISON WITH A LONG CHAIN FATTY ACID.

(E.) Bach, A.; Phan, T.; Metais, P. (Civil Hosp., Strasbourg, France). *Arch. Int. Physiol. Biochim.* 83(1):99-109, 1975.

The effects of octanoic acid and palmitoleic acid on hepatic metabolism were studied in the perfused livers of nonfasted male Wistar rats. The livers were perfused *in vitro* with lactic acid alone (10 mM/liter) or in combination with octanoic acid or palmitoleic acid (1.2 or 2.4 mM/liter). The pH was maintained constant at 7.40 and the neutralized supernatant was assayed at 0, 10, 20, 40, 60, and 80 min for lactate, pyruvate, β-hydroxybutyrate, acetoacetate, and glucose. Lactate alone significantly increased the concentrations of glucose, acetoacetate, and β-hydroxybutyrate at 80 min. When octanoate (1.2 mM/liter) was added to the perfusate, there was a nonsignificant decrease in pyruvate (40 min), a slight but significant increase in glucose (80 min), and a substantial increase in acetoacetate and β-hydroxybutyrate (80 min). When the concentration of octanoate was doubled, a significant decrease in pyruvate (40 min) and a substantial increase in β-hydroxybutyrate (80 min) were observed; the production of glucose and acetoacetate were not further increased. Addition of palmitoleate to the medium caused a significant increase in the pyruvate concentration (80 min) with no increase in glucose production. Octanoic acid was as ketogenic as palmitoleic acid when the 2 fatty acids were compared molecule by molecule, but the former was more ketogenic when the comparison was made on the basis of an equal number of acetyl groups. The results indicate that fatty acids do not play an important role in the rapid control of hepatic gluconeogenesis.

5364 THE RESPONSE OF THE RAT LIVER TO ALTERATIONS IN TOTAL PORTAL BLOOD FLOW.

(E.) Weinbren, K.; Washington, S. L. A.; Smith, C. Y. (R. Postgrad. Med. Sch., London, England). *Br. J. Exp. Pathol.* 56(2):148-156, 1975.

The effects of changes in portal blood flow on the whole rat liver were studied. Male Wistar rats were subjected to a portacaval anastomosis, which left the liver entirely deprived of portal blood flow. After 1 week, the portal flow was reconstructed by ligating and dividing the portacaval anastomosis and re-anastomosing the portal vein to its original stump. The animals were fasted, injected i.p. with thymidine-6-^{3}H, and killed 24-72 hr later. Liver weights were lower in the rats subjected to portacaval anastomosis without reconstitution than in those in which the portal vein was reconstituted. In the animals bearing the anastomosis, there was a significant relative decrease in the weight of the anterior lobes compared with the posterior lobes; of the 2 posterior lobes, the right lobe weighed relatively more in relation to the omental lobe than in the control livers. Cell volumes were much reduced in the rats subjected to portacaval anastomosis, with values generally higher in the animals undergoing portal vein reconstitution than in those still bearing portacaval anastomoses. Specific activity of the liver DNA was also higher in the rats which had undergone reconstitution of the portal vein than in those in which the portacaval anastomosis was retained. Dye injection experiments indicated that the blood flowing through the reformed portal vein in the animals undergoing venous reconstitution reached all 4 liver lobes to a comparable degree. The results suggest that the predominant reaction to portacaval anastomosis was hypertrophy with a minor hyperplastic component. They support the view that the response after partial hepatectomy may represent a summation of reactions to different components of the rather complex stimulus engendered by that procedure.

5365 PLASMA CONCENTRATION OF LIPOPROTEIN-X (LP-X) IN EXPERIMENTAL BILE DUCT OBSTRUCTION.

(E.) Ritland, S.; Bergan, A. (Univ. Hosp., Rikshospitalet, Oslo 1, Norway). *Scand. J. Gastroenterol.* 10(1):17-24, 1975.

Plasma levels of lipoprotein X were studied in bile duct-ligated mongrel dogs (six) with and without cholecystectomy. Dogs were divided into groups: dogs in groups I, IV, and VI had the common bile ducts ligated and cholecystectomy in the same session; dogs in groups II and V had bile duct ligation without cholecystectomy; dogs in group III had the common bile duct dissected free, but without bile duct ligation or cholecystectomy. Sequential quantitative determinations of lipoprotein X, measurements of plasma lipids, the initial rate of cholesterol esterification and liver function tests were performed. The lipoprotein appeared 11 to 21 hr after operation in the bile duct ligated and cholecystectomized dogs, and in dogs with preserved gallbladders 32 hr after operation. The lipoprotein levels were much higher in the cholecystectomized dogs throughout the observation periods (6-41 days) than in those with preserved gallbladders. Lipoprotein X concentration curves in plasma were biphasic in most of the bile duct-obstructed dogs. The first peak after 1-5 days was followed by a fall, and 10-14 days after operation another rise was observed. Fluctuations in the phospholipid and free cholesterol levels occured along with the changes in the lipoprotein. An inverse relation was determined between lipoprotein X and the activity of the lecithin: cholesterol acyltransferase ratio. It is suggested that the changes in plasma lipids during the first days following bile duct obstruction are initiated by abrupt reflux of phospholipids into plasma.

5366 PERSISTENT EFFECTS OF CHENODEOXYCHOLIC ACID ON BILIARY LIPIDS IN THE HAMSTER.

(E.) Goldstein, L. I.; Bonorris, G. G.; Coyne, M. J.; Schoenfield, L. J. (Cedars-Sinai Med. Cent., Los Angeles, Calif.). *J. Lab. Clin. Med.* 85(6): 1032-1041, 1975.

The effects of chenodeoxycholic acid (CDC) ingestion on the biliary lipid composition, the rate-limiting enzymes involved in hepatic cholesterol and bile acid synthesis, and the synthesis of hepatic cholesterol and bile acids were studied in male Syrian golden hamsters to determine the mechanism and duration of the cholesterol desaturation action of CDC. The hamsters were given 20 mg/kg/day of CDC dissolved in 16% ethanol by feeding tube; controls were given the vehicle alone. The animals were killed at the end of the 30-day feeding period or at 10-day intervals thereafter, and the gallbladders and livers were removed for analysis. Administration of CDC for 30 days significantly increased the biliary bile acid and lecithin:cholesterol ratio, as well as the percentage of CDC in the bile. These effects persisted for 20 days after termination of CDC feeding but were not evident after 30 days. The hepatic HMG coenzyme A reductase and 7α-hydroxylase activities were significantly reduced by CDC; these effects persisted for 10, but not 20, days after the end of CDC treatment. CDC had no effect on hepatic cholesterol, although the hepatic CDC concentrations were significantly elevated throughout the experiment. The results suggest that CDC has a salutory effect on the biliary lipid composition while causing an increase in exogenous biliary CDC and a decrease in the endogenous synthesis of cholesterol. The persistence of decreased cholesterol synthesis and of improved biliary lipid composition after discontinuing CDC treatment provides a rationale for studying this effect in man and for testing intermittent CDC regimes for gallstone dissolution.

5367 ETHANOL-INDUCED CROSS TOLERANCE TO SEVERAL HOMOLOGOUS ALCOHOLS IN THE RAT. *(E.)*

LeBlanc, A. E.; Kalant, H. (Addict. Res. Found. Ontario, Toronto, Canada). *Toxicol. Appl. Pharmacol.* 32(1):123-128, 1975.

Ethanol-induced cross tolerances to several lower aliphatic alcohols were studied in male Wistar rats. The animals were trained on the moving belt test which requires them to remain on a motor-driven belt which moves continuously over a shock-grid; if the animal touches the grid it receives a shock. The rats were then given a test dose of ethanol, *n*-propanol, *iso*-propanol, *n*-butanol, or *t*-butanol and tested on the moving belt, after which the ethanol-treated rats and a group of previously untreated rats were started on daily gavage with ethanol (6 mg/kg) for 20 days. At the end of this period, the rats were given test doses of ethanol and the other 4 alcohols and once again tested on the moving belt. The blood alcohol concentrations produced by the various doses of each alcohol were not significantly different in the pre- and postethanol groups; there was a linear correlation between dose and blood concentration in each case. This relation was not altered by chronic ethanol treatment. When the doses were corrected by the respective thermodynamic activity coefficients of the various alcohols, almost identical dose-response curves were obtained prior to chronic ethanol treatment. After chronic ethanol administration, the rats showed complete cross-tolerance to ethanol and the other alcohols; all of the corrected dose-response curves shifted to the same degree. This was not due to metabolic or distribution factors, which indicates that the findings reflect cross-tolerance in the nervous system itself. Thus, the effects of the various alcohols *in vivo* appear to depend on their common actions rather than on their unique actions, and involve complex integrative functions rather than the most basic membrane properties.

5368 ELECTRON MICROSCOPIC CYTOCHEMICAL CHARACTERIZATION OF BILE CANALICULI AND BILE DUCTS IN VITRO.

(E.) Oda, M.; Phillips, M. J. (Toronto Gen. Hosp., Canada). *Virchows Arch. [Zellpathol.]* 18(2):109-118, 1975.

Subcellular fractions from liver homogenates were used for cytochemical analysis of Mg^{++} ATPase and 5'-nucleotidase (AMPase). Liver tissue from Wistar rats was homogenized and the bile canaliculus-rich, and bile duct fractions isolated. Lead nitrate (200 mM) was used as the capture agent and 2 mM ATP or 5'-AMP as the substrate. After incubation, the suspension was centrifuged, fixed in glutaraldehyde, incubated, and postfixed in osmium tetroxide. Freshly prepared bile canaliculus or bile duct containing fractions were also prefixed in glutaraldehyde, recentrifuged, and postfixed in osmium tetroxide. Control fractions, prefixed or non-prefixed, were incubated without lead nitrate or substrate. Isolated bile canaliculi came through structurally intact, as did the bile ducts. The latter were usually surrounded by a basement membrane and partially disrupted hepatocytes. None of the controls showed electron-dense reaction products. Both prefixed and non-prefixed canaliculi showed Mg^{++} ATPase activity predominantly on the microvilli, though fine structural preservation was better in the prefixed specimens. Activity was also found on the canalicular microvilli of the partially disrupted hepatocytes, but not on the bile duct microvilli. The reaction products appeared to be deposited on the outer luminal surfaces of the canalicular membranes in the prefixed specimens. The non-prefixed canaliculi showed intense AMPase activity on the microvilli, and less intense activity on the lateral hepatic plasma membranes. There was a light reaction on vesicles presumably derived from fragmented plasma membranes. Demonstrable AMPase activity was dependent on duration of fixation. AMPase activity in the prefixed preparations was located primarily on the outer microvillar surfaces, and to a much lesser extent on the lateral plasma membranes and vesicles. No activity was seen on the microvilli or lateral or basal membranes of the bile ducts. No intracytoplasmic organelles showed activity of either AMPase or Mg^{++} ATPase. It is concluded that study of subcellular fractions is advantageous over study of whole liver tissue, and that the bile canalicular membrane is specialized for secretion of bile constituents from the cells into the canalicular lumens.

5369 THE EFFECTS OF ACUTE CADMIUM ADMINISTRATION IN THE LIVER AND KIDNEY OF THE RAT: LIGHT AND ELECTRON MICROSCOPIC STUDIES.

(E.) Hoffmann, E. O.; Cook, J. A.; Di Luzio, N. R.; Coover, J. A. (Louisiana State Univ. Sch. Med., New Orleans). *Lab. Invest.* 32(5):655-664, 1975.

Rat liver and kidney cells were studied by light and electron microscopy after injection of cadmium acetate. Charles River rats were injected i.v. with 0.600 mg cadmium acetate/100 g 5% dextrose, *via* the dorsal vein of the penis. Controls were given dextrose solution only. For light microscopy, rats were killed at 4, 8, and 16 hr. Liver and kidney slices were fixed and stained in hematoxylin and eosin (6 μm sections) or Paragon multiple stain (1 μm sections). For electron microscopy, rats were killed at 8 hr, and fragments of liver only were fixed in paraformaldehyde-*s*-collidine buffer, postfixed in osmium tetroxide, and stained with uranyl acetate and lead citrate. Mortality was 0% at 4 hr, and 5% at 16 hr. Light microscopy showed insignificant changes in the kidneys. The liver appeared normal after 4 hr, but by 8 hr early lesions occurred in 50% of the rats, and at 16 hr, 90-95% showed scattered single parenchymal necrosis, congestion, and mild Kupffer cell vacuolation. There was a mild inflammatory cell infiltrate. Some rats dying before 16 hr showed necrosis, apparently in the mid-lobular zone. Electron microscope examination of Kupffer cells showed vacuoles, increase in dilated smooth endoplasmic reticulum, swelling of mitochondria, and cytoplasmic degradation. Desquamation was evident and polyribosomes were more prominent than in controls. Deposits of fibrin, platelets, cellular debris, inflammatory cells, and precipitated protein were found in the sinusoidal and Disse's spaces. Electron dense collagen fibers were observed in these areas. Scattered individual hepatocytes showed necrosis and areas of cytoplasmic degeneration. Many showed an increase in cytoplasmic vacuoles attributable to phagosomes, proliferation and dilation of smooth endoplasmic reticulum, pinocytotic vacuoles usually located toward the sinusoids and Disse's spaces, and lipid droplets. There was also detachment of ribosomes, fragmentation of membranes, and dilation of rough endoplasmic reticulum. Some cells showed more polyribosomes and loose ribosomes than controls, and occasional mitochondria were impregnated and swollen. Glycogen was consistently absent from hepatocytic cytoplasm. It is concluded that the lesions are similar to those produced by certain other non-metallic hepatotoxins.

5370 ANIMAL MODEL: CHOLELITHIASIS IN BRAZILIAN SQUIRREL MONKEYS (Saimiri sciureus).

(E.) Lofland, H. B. (Bowman Gray Sch. Med., Winston-Salem, N.C.). *Am. J. Pathol.* 79(3):619-622, 1975.

Dietary factors in cholelithiasis were studied in the Brazilian squirrel monkey. Monkeys fed diets containing cholesterol and polyunsaturated fats for a period of nine months had almost 100% incidence of cholelithiasis. In monkeys fed cholesterol and safflower oil, 8/9 developed stones; in animals fed butter, 3/7 were affected; in those fed coconut oil, 1/7 was affected. Isotopic studies showed that the butter-fed animals had the largest bile acid pool size, and slowest turnover rate, while those fed safflower oil had the fastest turnover and the smallest pool size. Those fed coconut oil had a small pool size not differing significantly from the safflower oil-fed monkeys. The exacerbation of the disease by polyunsaturates in the monkeys resembles that in man. It is concluded that frequency of stone formation in the squirrel monkey is inversely related to the plasma cholesterol concentration, and provides a suitable model for the disease in man.

5371 BILIARY LIPIDS DURING VITAMIN C FEEDING IN HEALTHY PERSONS.

(E.) Pederson, L. (Aalborg Hosp. North, Denmark). *Scand. J. Gastroenterol.* 10(3):311-314, 1975.

The influence of vitamin C on biliary lipids was studied in 10 healthy patients. None had taken vitamin C apart from dietary sources for at least one yr. Fasting duodenal bile samples were obtained by duodenal intubation after cholecystokinin stimulation. Plasma samples were obtained simultaneously. During the following 10-15 days, each subject took 1 g vitamin C daily in divided doses; then fresh bile and plasma samples were obtained. Total bile acids, cholesterol and biliary phospholipids were determined. Percent concentrations of individual lipids in relation to total biliary lipids, the molar ratio between cholesterol and bile acids and the molar ratio between cholesterol and bile acids plus phospholipids were calculated. Differences between all values before and after treatment with vitamin C were statistically insignificant. It is concluded that vitamin C probably has no influence on biliary lipid composition in healthy humans.

5372 PROTEIN SYNTHESIS IN MITOCHONDRIA AND MICROSOMAL FRACTIONS FROM RAT BRAIN AND LIVER AFTER ACUTE OR CHRONIC ETHANOL ADMINISTRATION.

(E.) Renis, M.; Giovine, A.; Bertolino, A. (Psychiatric Hosp., Casa Divina Provvidenza, Bisceglie (Bari), Italy). *Life Sci.* 16(9):1447-1458, 1975.

The effects of ethanol on the protein synthesizing capacity of the brain was studied in young male Wistar rats. Ethanol was administered to the rats for 20-25 days in the drinking water (20% ethanol) or was administered p.o. by stomach tube (5 g/kg) 3 hr before sacrifice. Incorporation of ^{14}C- or ^{3}H-leucine into brain and liver microsomes and mitochondria was determined *in vivo* and *in vitro*. For the study of protein synthesis *in vivo*, rats were sacrificed 1/2 hr after i.p. injection of ^{3}H-leucine. Protein synthesis in the mitochondrial preparations was significantly inhibited by chloramphenicol and practically unaffected by cycloheximide; the latter, however, specifically inhibited the microsomal preparations. Chronic ethanol administration increased *in vitro* protein synthesis in liver microsomes and mitochondria, while acute ethanol treatment inhibited it. Ethanol administration had no significant effects on protein synthesis in brain mitochondria, although chronic treatment had an inhibitory effect on brain microsomal preparations. The ethanol effect on liver microsomes was noticeably extended at the ribosomal level, as indicated by measurements of ^{3}H-leucine incorporation in isolated microsomes crossed with pH 5 enzymes from rat liver and brain after chronic ethanol treatment. Acute ethanol treatment decreased the *in vivo* incorporation of radioactive leucine into liver mitochondria and brain and liver microsomes, with no significant effects on brain mitochondria. Chronic administration had no significant effects on *in vivo* protein synthesis. These results indicate that ethanol affects protein synthesis *in vitro* only after chronic administration; the effects are opposite in the brain and liver but similar in the microsomal and mitochondrial fractions of each organ.

5373 ISOLATION OF CENTROLOBULAR AND PERILOBULAR HEPATOCYTES AFTER PHENOBARBITAL TREATMENT.

(E.) Wanson, J. C.; Drochmans, P.; May, C.; Penasse, W.; Popowski, A. (Lab. Cytol. Exp. Oncol., Free Univ., Brussels, Belgium). *J. Cell Biol.* 66(11):23-41, 1975.

I.p. phenobarbital injections (100 mg/kg/day for 3-7 days) were used to induce a clear selective response in the centrolobular hepatocytes of adult female Sprague-Dawley rats. Following phenobarbital treatment, the hepatocytes were examined by electron microscopy, and their protein, DNA, RNA, and glycogen concentrations and glucose-6-phosphatase activities determined. The phenobarbital injections induced an intense proliferation of the smooth endoplasmic reticulum (ER) associated with a decrease in the activity of glucose-6-phosphatase. The centrolobular hepatocytes were the first affected, leading to an enhancement of liver lobule heterogeneity. Two liver cell populations were distinguished following subfractionation of the hepatocytes on Ficoll density gradients: light hepatocytes (mean density 1.10), which had the same morphological characteristics as the centrolobular cells, i.e., an abundant smooth ER composed of tubular elements, numerous small mitochondria, and few glycogen particles; and heavy hepatocytes (mean density 1.14), which were characterized by large and compact glycogen areas and prominent rough endoplasmic cisternae, as are the perilobular cells. After incubation in Wachstein-Meisel medium, the centrolobular hepatocytes exhibited dispersed reaction sites of glucose-6-phosphatase activity, whereas the periolobular cells showed a continuous and intense reaction pattern. Morphometric determinations showed the centrolobular phenobarbital hepatocytes to be considerably enlarged (mean diameter: 23.7 μm); the perilobular hepatocytes had a significantly smaller mean diameter of 19.2 μm, which is close to the values of control liver cells.

5374 COLCHICINE INHIBITION OF PLASMA PROTEIN RELEASE FROM RAT HEPATOCYTES.

(E.) Redman, C. M.; Banerjee, D.; Howell, K.; Palade, G. E. (New York Blood Cent., N.Y.). *J. Cell Biol.* 66(1): 42-59, 1975.

The effects of colchicine and functionally related agents on the *in vitro* and *in vivo* secretion of albumin and other plasma proteins by the rat liver were studied. Ethanol (0.6 g/100 g of a 50% solution) was given p.o. by stomach tube to fasted male rats, after which colchicine or radioactive amino acid was administered i.v. *In vitro*, rat liver slices were incubated with radioactive leucine, washed, and transferred to a "chase" medium containing nonradioactive amino acids and colchicine or vinblastine. Radioactivity in the albumin and other plasma proteins was determined by immunoprecipitation, and liver samples from the rats treated *in vivo* were examined by electron microscopy. Colchicine inhibited the secretion of albumin and other plasma proteins both *in vitro* and *in vivo*. *In vitro* secretion of these proteins by the rat liver slices was inhibited by doses as low as 10^{-6} M, the maximal effect occurring at 10^{-5} M. Inhibition of secretion was accompanied by a concomitant retention of nonsecreted proteins within the slices. Colchicine did not inhibit protein synthesis at these concentrations. Vinblastine also inhibited plasma protein secretion, while lumicolchicine, griseofulvin, and cytochalasin B had no such effect. The inhibition of secretion by colchicine and vinblastine was not due to changes in the intracellular nucleotide phosphate levels. When administered i.v. at 10-25 μM/100 g, colchicine acted within 2 min and its inhibitory effect lasted for at least 3 hr. This agent had no effect on the transport of secretory proteins in the rough or smooth endoplasmic reticulum, but it caused these proteins to accumulate in the Golgi-derived secretory vesicles. Neither the concentration nor the arrangement of microtubules within the Golgi regions appeared to be affected by colchicine at the concentrations used. The results indicate that colchicine acts by hampering the discharge of secretory proteins from Golgi-derived secretory vacuoles into the space of Disse.

5375 ISOLATION AND SUBFRACTIONATION ON FICOLL GRADIENTS OF ADULT RAT HEPATOCYTES: SIZE, MORPHOLOGY, AND BIOCHEMICAL CHARACTERISTICS OF CELL FRACTIONS. *(E.)* Drochmans, P.; Wanson, J. C.; Mosselmans, R. (Lab. Cytol. Exp. Oncol., Free Univ., Brussels, Belgium). *J. Cell Biol.* 66(1):1-22, 1975.

A technique for the isolation and subfractionation of adult rat hepatocytes is described. The recirculating perfusion of rat liver with a Ca^{++}-free Hank's solution produced a release of the adhesiveness of the cells and a cleaving of the desmosomes. The subsequent addition of collagenase and hyaluronidase to the perfusion medium led to a complete dissociation of the liver tissue into a mixture of isolated cells and cell cords in which the hepatocytes remained connected with specific junctional differentiations, namely the gap and tight junctions. Individual cells were released by submitting the suspension of cell trabeculae to a gentle rolling. The gap junctions were thereby ruptured, generally remaining attached to one cell and taking with them a small portion of cytoplasm. In this manner, 60-65% of the liver parenchymal cells were isolated; endothelial cells and other cells of the connective tissue were not recovered. The ultrastructural preservation of the isolated hepatocytes was excellent and the glucose-6-phosphatase activity appeared unaltered in most cases. Protein, DNA, and RNA recovery in the preparations was also satisfactory, amounting to 70% of that found in liver homogenate; glycogen was partly lost or degraded during the manipulations. Measurements of cell diameter confirmed the preservation of the original volume of the *in situ* hepatocytes and the presence of more than 1 type of parenchymal cell. By submitting this heterogeneous cell population to an isopycnic density gradient centrifugation, 2 types of hepatocytes were distinguished: the light hepatocytes, with a mean diameter of 20.5 μm and a mean density of 1.10, were characterized by an extended smooth endoplasmic reticulum entrapping dispersed α-glycogen particles; the heavy hepatocytes, with a mean diameter of 19.0 μm and a mean density of 1.14, presented a relatively reduced compartment of smooth endoplasmic reticulum and large accumulations of glycogen. It is suggested that the low-density cell fraction corresponds to centrolobular cells and the high-density fraction to periolobular hepatocytes.

5376 IMPAIRED HEPATIC RELEASE OF TRIGLYCERIDES: A POSSIBLE CAUSE OF ACUTE ALCOHOLIC FATTY LIVER IN THE RHESUS MONKEY. *(E.)* Nair, C. R.; Nirankari, O. P.; Chhuttani, P. N.; Datta, D. V. (Postgrad. Inst. Med. Educ. Res., Chandigarh, India). *Clin. Sci. Mol. Med.* 48(5):453-455, 1975.

The effects of Triton WR-1339 on the plasma triglycerides of ethanol-treated Rhesus monkeys were studied to determine the mechanism involved in the development of acute alcoholic fatty liver. Well-nourished Rhesus monkeys with no histological evidence of liver disease received an infusion of sodium chloride for 30 min followed by an i.v. infusion of Triton WR-1339 (20% solution at a rate of 26.6 mg/min/kg for 10 min). In some animals, the Triton WR-1339 infusion was preceded by a 30-min i.v. infusion of ethanol (214 mM/liter in saline at a rate of 1.8 mM/min/kg). Blood samples were collected 0, 2, 4, and 6 hr after the end of the Triton infusion, and the plasma triglycerides, plasma Triton, and blood ethanol levels were estimated. Liver biopsy tissue was also examined histologically and the liver triglycerides measured. In addition, the inhibitory effect of Triton on plasma lipoprotein lipase was studied *in vitro*. In the saline-Triton group, the plasma triglycerides rose 10- to 19-fold over basal values by the sixth hr; the liver triglyceride levels remained normal. In contrast, the ethanol-Triton group showed only a 1.2- to 2.3-fold rise in plasma triglycerides, with a significant rise in the liver triglycerides. Ethanol had no significant effect on the plasma Triton concentration, and inhibition of lipolysis was 94% in the saline-Triton group compared with 93.5% in the ethanol-Triton group. It is suggested that the reductive effect of Triton on the plasma triglycerides following ethanol administration is due to a reduced release of triglyceride from the liver. Acute alcoholic fatty liver in Rhesus monkeys is probably due to impairment in the hepatic release of triglycerides.

5377 EFFECT OF CHRONIC INTAKE OF ETHANOL ON LACTATE/PYRUVATE AND β-HYDROXYBUTYRATE/ACETOACETATE RATIOS IN RAT LIVER. *(E.)* Khanna, J. M.; Kalant, H.; Loth, J. (Dep. Pharmacol., Univ. Toronto, Canada). *Can. J. Physiol. Pharmacol.* 53(2):299-303, 1975.

Lactate/pyruvate and β-hydroxybutyrate/acetoacetate ratios were measured in male Wistar rats chronically treated with ethanol. The experimental rats were fed a liquid diet providing 35% of the calories as ethanol, while pair-fed controls received a similar diet in which the alcohol was replaced by an equicaloric concentration of sucrose. The ethanol diet was discontinued immediately, 24 hr, or 48 hr before sacrifice (1 month after the beginning of the experiment). In some animals in which the ethanol feeding was terminated 48 hr prior to sacrifice, and in their controls, ethanol (1 g/kg) was injected i.p. 1 or 3 hr before sacrifice. The lactate/pyruvate ratio was significantly higher in the ethanol-fed rats than in the controls when the ethanol diet was continued until sacrifice, but the two groups did not differ in this respect when the ethanol diet was discontinued prior to sacrifice. The β-hydroxybutyrate/

acetoacetate ratio was also significantly higher in the ethanol group when the ethanol diet was continued until the time of sacrifice; again, however, this difference disappeared when the ethanol feeding was discontinued 24 or 48 hr prior to sacrifice. In contrast, when ethanol was injected 1-3 hr before sacrifice, the β-hydroxybutyrate/acetoacetate ratio was significantly higher in the controls. The results are compatible with an adaptive increase in the mitochondrial reoxidation of NADH in the chronic alcohol groups, but the possibility of a change due to alcohol withdrawal cannot be excluded.

5378 ON THE QUANTITATIVE STEREO-MORPHOLOGY OF MICROBODIES IN RAT HEPATOCYTES. *(E.)* Wedel, F. P.; Berger, E. R. (VA Hosp., Brooklyn, N.Y.). *J. Ultrastruct. Res.* 51(2):153-165, 1975.

Microbodies in rat hepatocytes were studied quantitatively, stereologically, morphometrically, and ultrastructurally. Employing the modified Sjostrand technique for 3-dimensional reconstructions from serial thin sections for electron microscopy, two populations of particles were revealed. The larger class P microbodies were spherical particles, about 410 nm in diameter, and bounded by a limiting membrane about 110 Å thick; they contained a finely granular matrix with a dense nucleoid and constituted approximately 1.1% of the hepatic cytoplasm. The smaller class Q particles were also spherical and about 260 nm in diameter. They contained a granular matrix but lacked a nucleoid and their limiting membrane was trilaminar and about 130 Å in thickness. These particles constituted about 0.1-0.2% of the hepatic cytoplasm. While it is likely that the class P microbodies are peroxisomal, there is no morphological evidence to suggest that the class Q particles are small or immature peroxisomes. It is possible that the class Q microbodies are lysosomal or that they are a distinct population of hepatic cytoplasmic organelles which have not previously been described.

5379 EFFECT OF MODIFICATION OF THYROID FUNCTION ON CHOLESTEROL 7α-HYDROXYLATION IN RAT LIVER. *(E.)* Takeuchi, N.; Ito, M.; Uchida, K.; Yamamura, Y. (Osaka Univ. Hosp., Japan). *Biochem. J.* 148(3):499-503, 1975.

The effect of p.o. glucose or cholesterol administration on hepatic cholesterol synthesis and cholesterol 7α-hydroxylation was studied in hyper- and hypothyroid rats. Female Sprague-Dawley rats were fed desiccated thyroid powder (6, 18, or 54 mg/day for 10 days) to make them hyperthyroid or were fed 2-thiouracil (75 or 100 mg/day for 10 days) to make them hypothyroid. The rats were then starved and given 2 ml of 50% glucose solution/100 g and killed 3 hr later, or were given a cholesterol suspension in peanut oil (2 ml/100 g of 1.3 g cholesterol and 0.3 g cholic acid in 40 ml peanut oil) daily for 3 days. The thyroid powder and thiouracil treatments were continued during cholesterol administration. Glucose-induced increases in cholesterol synthesis and 7α-hydroxylation were enhanced by pretreatment with thyroid powder and suppressed by pretreatment with thiouracil. The enhancement of 7α-hydroxylation was produced by a relatively small amount of thyroid powder (6-18 mg), while high doses were required to increase cholesterol synthesis. In contrast, 7α-hydroxylation was suppressed by 50-75 mg thiouracil, much higher doses being required to decrease cholesterol synthesis. Although cholesterol synthesis was increased to a similar degree in both hypo- and hyperthyroid rats after glucose administration, hydroxylase activity in the hypothyroid rats increased more slowly and attained a lower maximum level than in the hyperthyroid rats. It is concluded that cholesterol 7α-hydroxylase activity is more sensitive to thyroid function than are the activities of cholesterol-synthetic enzymes. When exogeneous cholesterol was given, the hypothyroid rats showed a larger increase in the serum cholesterol concentration than the hyperthyroid rats, and there was an inverse relation between the serum cholesterol concentrations and hepatic cholesterol 7α-hydroxylase activities.

5380 MORPHOLOGICAL ALTERATION THROUGH CHANGES IN RESPIRATORY ENZYME LEVELS IN THE LIVER MITOCHONDRIA OF JAUNDICED PATIENTS. *(E.)* Takasan, H.; Yamada, T.; Ozawa, K.; Honjo, I. (Kyoto Univ. Sch. Med., Japan). *J. Electron Microsc. (Tokyo)* 24(1):19-32, 1975.

Morphological and biochemical alterations in the liver mitochondria of 20 patients with obstructive jaundice were studied. Sectioned biopsy specimens were examined by electron microscopy and mitochondrial preparations were examined in terms of phosphorylative efficiency and oxygen utilization; the respiratory enzymes of the liver mitochondria were also assayed using spectrophotometric techniques. The patients were classified into 3 groups according to the concentrations of cytochrome a(+a_3) in their liver mitochondria: in group I, the cytochrome a(+a_3) concentration was 0.5-1.0 x 10^{-10} M/mg mitochondrial protein; in group II, the concentration was over 1.0 x 10^{-10} M/mg; and in group III, the concentration was less than 0.5 x 10^{-10} M/mg. In 6 of the 9 group I patients, the absolute phosphorylative activities of the liver mitochondria were substantially above control values and the phosphorylative activities/U of cytochrome a(+a_3) were enhanced. In 6 of the 8 group II patients, the absolute phosphorylative activities were slightly reduced below control levels and the phosphorylative activities/U of cytochrome a(+a_3) were inhibited. In 4 patients in group III, both the absolute phosphorylative activities and the phosphorylative activities/U of cytochrome a(+a_3) were severely inhibited. Morphologically, the mitochondria in group I were round or oval in shape with an electron-lucent matrix. In group II the mitochondria were enlarged and there were increased numbers of cristae; giant- or mega-mitochondria were frequently observed. In group III, the mitochondrial cristae were decreased in number and showed an irregular arrangement; the matrix was also decreased in density with a loss of intramitochondrial granules and swelling. The various morphological changes seen in the liver mitochondria of groups I and II, including the appearance of partition- and mega-mitochondria, appeared to represent a series of adaptive phenomena for maintaining intracellular energy metabolism in obstructive jaundice.

5381 THE EFFECT OF PROSTAGLANDIN A_1 AND E_1 ON CANINE HEPATIC BILE FLOW.

(E.) Kaminski, D. L.; Ruwart, M.; Willman, V. L. (St. Louis Univ. Sch. Med., Mo.). *J. Surg. Res.* 18(4):391-397, 1975.

The effects of prostaglandins A_1 and E_1 on the excretion of bile salt, secretin, and cholecystokinin-stimulated hepatic bile flow were studied in dogs with chronic biliary and gastric fistulas. The dogs received a continuous i.v. infusion of 0.15 M NaCl solution or of a sodium taurocholate solution (18 μM/min). In some cases, secretin (2 U/kg/hr) or CCK-octapeptide (4 μg/kg/hr) was infused with the bile salt. The prostaglandins (2.5 μg/kg/min) were given simultaneously through separate i.v. lines. The bile and gastric secretions were collected and measured throughout the infusion periods. PGA_1 infusion caused an increase in bile volume and in both bicarbonate concentration and output; bile salt concentration was decreased and sodium and chloride output increased. Similar effects were obtained with PGE_1 infusion, although the change in bile volume was not significant. PGA_1 administered during secretin-stimulated bile flow resulted in a significant inhibition of bile flow and sodium output and a significant increase in the bicarbonate and bile salt concentrations. PGE_1 significantly increased the bile salt output and concentration under these conditions but did not affect the volume or electrolyte composition of the bile. PGE_1 inhibited the CCK-octapeptide-stimulated gastric fistular hydrogen ion output by 54.6% and significantly decreased the bile salt concentration. PGA_1 inhibited the CCK-octapeptide-stimulated gastric acid response by 40.2% and increased the sodium output and concentration but had no significant effect on bile volume. At no time did the pH of the duodenal fluid fall below 5.0. The data indicate that PGE_1 and PGA_1 are potent inhibitors of gastric acid secretion and that they are effective inhibitors of CCK-octapeptide-stimulated hydrogen ion output and pentagastrin-stimulated hydrogen ion output.

5382 EFFECT OF EXOGENOUS CYTOCHROME C ON OXIDATIVE PHOSPHORYLATION IN RAT LIVER IN ACUTE TOXIC HEPATITIS.

(Rus.) Slepneva, L. B.; Krivoruchko, B. I. (Res. Inst. Hematol. Blood Transf., Leningrad, USSR). *Biull. Eksp. Biol. Med.* 77(6):46-48, 1974.

The effect of parenteral administration of cytochrome C on processes of oxidative phosphorylation in the liver of rats with acute toxic hepatitis, caused by a single subcutaneous injection of CCl_4, was studied. Experimental rats (160-220 g) were divided into 3 groups. Into the rats of the first group a 0.25 ml/100 g dose of 40% peach oil solution of CCl_4 was injected and the animals were killed 1, 3, or 7 days after the injection. Rats of the second group received daily injections of 10 mg/1 kg of cytochrome C beginning from the day of the CCl_4 injection. Instead of CCl_4 and cytochrome C, the third (control) group of rats were injected with equivalent volumes of peach oil and physiological solution. Results indicated that parenteral introduction of cytochrome C during acute intoxication by CCl_4 leads to an increase in intensity of the processes of respiration and phosphorylation in homogenates of rat liver and to the increase in intensity of conjugation of these processes. It is concluded that stimulation of oxidative phosphorylation processes in tissue of rat liver during acute intoxication with CCl_4 and during introduction of cytochrome C might be connected with the penetration of cytochrome C into the cell and its direct effect on intracellular structure of the liver.

5383 EFFECT OF EXCESSIVE INGESTION OF DIFFERENT KINDS OF FATS ON LIPID COMPOSITION AND THE USE OF EXOGENOUS FATTY ACIDS IN LIPID SYNTHESIS.

(Rus.) Markelova, V. F.; Liapkov, B. G. (Inst. Nutr. USSR Acad. Med. Sci., Moscow). *Vopr. Pitan.* (4):8-11, 1974.

The objective of the study was to elucidate the effect of prolonged feeding of rats with excessive quantities of various fats on the composition of lipids of liver and blood, and to determine under experimental conditions the degree of involvement of fatty acids in synthesis of glycerides, phospholipids, cholesterol and its ethers. The experimental male rats (140-160 g) were fed for 30 days with isocaloric rations of 60 kcal/100 g of wt. The typical ration of the control group rats consisted calorie-wise of 18% proteins, 56% carbohydrates, and 26% of lard or sunflower oil. During the course of experimentation, in order to retain isocaloric conditions, a fraction of fat in the rations of experimental rats was increased at the expense of carbohydrates. The results showed that prolonged feeding of rats with rations with excessive fat content led to the increase of lipids, glycerides and of ethers of cholesterol in the liver; it also led to intensification of synthesis of these compounds, which in turn led to a deficit of phospholipids, favoring the formation of lipodystrophy of liver.

5384 THE EFFECT OF HEPATIC ISCHEMIA ON LIVER FUNCTION AND THE RESTORATION OF LIVER MASS AFTER 70 PER CENT PARTIAL HEPATECTOMY IN THE DOG.

(E.) Mackenzie, R. J.; Furnival, C. M.; O'Keane, M. A.; Blumgart, L. H. (Wellcome Surg. Res. Inst., Univ. Glasgow, Scotland). *Br. J. Surg.* 62(6):431-437, 1975.

The effect of normothermic ischemia of the liver prior to resection was studied in relation to postoperative liver function and restoration of liver mass. Dogs (39) had partial hepatectomies to remove 70% of the liver including the left and central portions. In 17, the branches of the portal vein and hepatic artery supplying the caudate and right lateral lobes were occluded for 30, 45, or 60 min. At the end of each period after restoration of blood flow, portal hepatectomy was performed. In 17 dogs, partial hepatectomy only was performed, and in 5 controls, laparotomy (with handling of the viscera) only was performed. Serum bilirubin, alkaline phosphatase, SGPT, SGOT, total protein, albumin, and BSP retention were measured daily for 1 week postoperatively, and then weekly for 6 weeks. Of the 17 given partial hepatectomy only, 2 died from technical failure, 1 from unknown causes, and 3 developed obstructive jaundice. In the remaining 11, determinations were made. Alkaline phosphatase rose significantly to a peak of 290 U/liter at 1 week. Both SGOT and SGPT showed a large increase within 48 hr (300 mu/ml and 220 mu/ml, resp.) Total serum protein paralleled serum albumin, falling to its lowest value (35 g/liter) one week postoperatively. BSP retention was measured in eight dogs and showed an abnormal rise to 25% on the second postoperative day, followed by a return to normal. Liver restoration was 91% at the time of sacrifice and regenerated tissue was histologically normal. Of the 17 given ischemia plus partial hepatectomy, 15 survived. Serum alkaline phosphatase activity was elevated immediately after operation (130 U/liter), and in some dogs it continued to rise (360 U/liter by six weeks). SGOT and SGPT rose to peaks 48 hr after surgery (190 mu/ml, and 250 mu/ml, resp.). Serum total protein fell due to a fall in serum albumin, which reached its lowest value (29 g/liter) 3 days after surgery. BSP retention increased 24% on the 2nd day. Of the dogs, 7 also showed a late rise to 12-42% retention at various times between the 3rd and 6th weeks. Liver restoration was 83%. In the controls, SGOT rose to 99 mu/ml on the first day. Serum albumin fell, reaching a minimum value (34 g/liter) after 1 week. It is concluded that ischemia of the liver remnant for 1 hr before resection is compatible with survival in the dog.

5385 EARLY, REVERSIBLE PLASMA MEMBRANE INJURY IN GALACTOSAMINE-INDUCED LIVER CELL DEATH. *(E.)* El-Mofty, S. K.; Scrutton, M. C.; Serroni, A.; Nicolini, C.; Farber, J. (Temple Univ. Sch. Med., Philadelphia, Pa.). *Am. J. Pathol.* 79(3):579-596, 1975.

The role of plasma membranes in the pathogenesis of galactosamine-induced cell death was studied in the rat. Wistar rats injected i.p. with D-galactosamine (200 or 400 mg/kg), uridine (1.2 mg/g), glucosamine (400 mg/kg), or D,L-ethionine (1 mg/g). The rats were killed, the plasma membranes isolated from the livers, and 5'-nucleotidase, protein, glucose-6-phosphate, and cytochrome C oxidase determined. Membrane proteins were electrophoresed on polyacrylamide gels, and circular dichroism measurements were made of suspensions by spectropolarimeter. Liver samples were analyzed for calcium and copper content. Rates of *in vitro* nuclear RNA and protein synthesis were determined. The higher dose of galactosamine caused a 40% reduction in specific activity of 5'-nucleotidase in plasma membranes and markedly altered the circular dichroism of the membranes, as indicated by a 2-fold increase in maximum negative ellipticity at 22 nm (from -5680 to -9050). These effects were not seen in rats given the lower dose of galactosamine. Neither glucosamine nor ethionine caused cell death; 5'-nucleotidase activity was not inhibited in glucosamine-treated rats. Uridine administered simultaneously with galactosamine prevented the alterations in both 5'-nucleotidase and circular dichroism. Administration of uridine 2-2 1/2 hr after galactosamine reversed the inhibition of 5'-nucleotidase and significantly reduced the maximum negative ellipticity. Uridine could not reverse the membrane alterations after 3 hr, but it did reverse the inhibition of RNA and protein synthesis 6 hr after injection of 400 mg/kg galactosamine. Liver calcium levels rose from 2 hr following either 200 or 400 mg/kg galactosamine. With the higher dose, the calcium content remained constant at 3-4 hr and then rose sharply to a peak of 4 times the initial values at 12 hr. At 12-24 hr the level declined to twice the initial value. With the lower dose, the calcium level declined at 3-4 hr and then rose slightly to a peak value of less than twice the initial level by 12 hr. Copper content was not affected by galactosamine. Ethionine and glucosamine did not induce a rise in calcium content. It is concluded that necrogenic doses of galactosamine produce early changes in rat liver plasma membranes and in total cell calcium ions.

5386 TOXICITY OF CHENODEOXYCHOLIC ACID IN THE NONHUMAN PRIMATE. *(E.)* Morrissey, K. P.; McSherry, C. K.; Swarm, R. L.; Nieman, W. H.; Deitrick, J. E. (New York Hosp.-Cornell Med. Cent., New York, N.Y.). *Surgery* 77(6):851-860, 1975.

The toxicity of chenodeoxycholic acid was studied in the baboon. Pregnant and nonpregnant female baboons (*Papio anubis* and *P. cyanocephalus*) had the gallbladder sutured to the anterior abdominal wall during exploratory laparotomy, and were assigned to control (8) or chenodeoxycholic acid-treated groups (10). The treated group was given 18 mg/kg/day chenodeoxycholic acid in 0.5 cc ethanol in an orange, while controls were given oranges with ethanol only. Over a 6-month period the treated group was divided into a low-dose group of 2 baboons given 20 mg/kg/day for 14 months; an incremental-dose group of 10 which were progressed by 2 mg/week from 18 to 38 mg/kg/day over 2 1/2 months in a total experimental period of 15 months; and a high-dose group of 6 given 38 mg/kg/day for 8 months. Animals were observed daily for well-being, behavior, menstruation, food consumption, and character of food droppings or excreta. Weight and clinical chemistry were determined monthly. Percutaneous liver biopsies and gallbladder bile aspirates were obtained periodically. Bile pool salt size was determined in 1/2 of the control and experimental groups by isotope dilution kinetic techniques. There were no gross clinical changes in the experimental group throughout the study period. Percentages of chenodeoxycholic and lithocholic acids in the bile increased significantly in all treated animals. Those in the high-dose group showed maximum increases to over 80% chenodeoxycholic and 9% lithocholic acids with 1 month of treatment. Those in the low-dose and incremental-dose groups required 2-10 months to develop similar changes. Cholic and deoxycholic pools decreased significantly after 1 yr. Treated animals showed an increase in chenodeoxycholic acid pools of 181-943 mg and a decrease in the cholic acid pool of from 302-114 mg. Serum bilirubin, total protein with albumin-globulin ratio, calcium, and phosphorus remained normal. Serum cholesterol varied as a function of pregnancy in all animals. Treatment had no effect on serum cholesterol or cholesterol pool size. The SGPT, SGOT, 5'-nucleotidase, and alkaline phosphatase tests were good indicators of response to treatment. Of the 18 treated animals, 15 developed SGOT or SGPT levels over 75 IU and moderate to severe lesions. The low- and increment-dose animals took 5-11 months to reach this point, while the high-dose group took 1 1/2-3 months. In 9 the changes occurred synchronously and were accompanied by elevations of 5'-nucleotidase and alkaline phosphatase. When both enzymatic and histologic abnormalities had appeared in the 11, the percentage of chenodeoxycholic acid has risen to over 80% in 8, 60% in 2 and 45% in 1, and lithocholic acid had risen to 8-14%. It is concluded that chenodeoxycholic acid is hepatotoxic to baboons at 20-38 mg/kg/day.

5387 25-HYDROXYVITAMIN D_3: EVIDENCE OF AN ENTEROHEPATIC CIRCULATION IN MAN. *(E.)*

Arnaud, S. B.; Goldsmith, R. S.; Lambert, P. W.; Go, V. L. W. (Mayo Clin., Rochester, Minn.). *Proc. Soc. Exp. Biol. Med.* 149(2):570-572, 1975.

The intestinal and plasma distribution of i.v. administered 25-hydroxyvitamin D_3 was studied. Normal adults (3) were intubated with a triple-lumen nasoduodenal tube after an overnight fast. The first aperture was proximal to the ampulla of Vater, the second at the ligament of Treitz, and the third 30 cm distal to the second. Polyethylene glycol (5 g/liter) was perfused at 2 ml/min through the first lumen, and duodenal aspirates collected through the second for 30-36 hr. Samples were taken and reinfused through the third. Chromium sesquioxide (0.5 g daily) was started p.o. just prior to an i.v. bolus injection of 8-10 μCi of 26, 27-^{3}H-25-OH-D_3. Serial blood specimens and all urine and feces excreted for 12 days after injection were collected. Total ^{3}H in stool samples and duodenal aspirates were determined by liquid scintillation counting. Fecal data were corrected, on the basis of the chromium sesquioxide marker, to correspond to the appropriate blood and duodenal samples. To determine disappearance of ^{3}H-25-OH-D_3 from the blood, serum was extracted with methanol-chloroform, and chromatographed. Within 5 min of the injection of the labeled vitamin, 75-86% of the ^{3}H could be found in the plasma. During the first 6 hr, 45% of the dose disappeared from the plasma and 17.1% of the dose appeared in the duodenum. Plasma radioactivity dropped to 26.7% of the dose at 24 hr, while cumulative intestinal radioactivity doubled to 35.5%. Fecal radioactivity corresponding to the first 24.7 hr was 3.03% of the dose, indicating resorption of at least 85% in the duodenum. Total fecal excretion of ^{3}H (22.5% in 8.9 days) was much lower than the quantity of ^{3}H in the duodenum in the first 24 hr. Urinary excretion accounted for 1.47% after 24 hr, and 2.30% after 48 hr. The intestinal reabsorption of 25-hydroxyvitamin D_3 is indicative of an enterohepatic circulation that may be of physiologic importance. Interruption in the recycling of this vitamin D_3 metabolite may be an important mechanism of acquired vitamin D deficiency in gastrointestinal disease.

5388 DEUTERIUM TRANSFER FROM [1,1-^{2}H]ETHANOL DURING METABOLISM OF BILE ACIDS AND CYCLOHEXANONE IN THE ISOLATED PERFUSED RAT LIVER. *(E.)*

Cronholm, T.; Erliksson, H.; Matern, S.; Sjovall, J. (Kemiska Inst. Stockholm, Sweden). *Eur. J. Biochem.* 53(2):405-410, 1975.

Factors in the transfer of deuterium from (1,1-^{2}H)-ethanol to reduction products of cyclohexanone, 3-oxo-5β-cholanoic, and 3-oxo-4-cholenoic acids were studied in the isolated, perfused rat liver. Livers from Sprague-Dawley rats were perfused with 3-oxo-5β-cholanoic acid (males), or 3-oxo-4-cholenoic acid (females). The perfusate contained 12 ml blood diluted to 72 ml with Tyrode's solution, with a ^{2}H excess of 46 atoms% as ^2H_2O. Unlabeled or (1,1-^{2}H)-ethanol was added to give a concentration of 69 mM, and 1 mg 3-oxo-4-cholenoic acid or 1 mg 3-oxo-5β-(24-^{14}C) cholanoic acid (10^6 cpm) was added. Bile was collected in 1 hr portions, and lithocholic acid, 3-hydroxy-5β-cholanoic acid, and cyclohexyl glucuronide were extracted. With 3-oxo-5β-cholanoic acid as the substrate, lithocholic and chenodeoxycholic acids were usually found as metabolites, the former constituting 10-80% of the metabolites. No bile acids containing a 3-oxo group were found. Lithocholic acid formed from 3-oxo-5-β during (1,1-^{2}H)-ethanol perfusions contained 11% monodeuterated molecules, and none had more than one deuterium atom. Abundance of deuterated molecules was diminished by cycloserine or aminooxyacetate in the perfusion medium, and maleate, disulfiram, lactate, and malate caused a decrease in labeling. Abundance of monodeuterated cyclohexanol molecules was 49% during the metabolism of the labeled ethanol. Deuterium excess in cyclohexanol was increased by maleate, lactate, malate, and oleate. Abundance of monodeuterated lithocholic acid molecules formed in ^2H_2O medium (46 atoms % excess) was 26%, and an insignificant number had more than one deuterium atom. When the acid was oxidized and the product converted to *O*-methyloxime, abundance of monodeuterated molecules decreased to 2.8%, showing most of the deuterium in the acid was in the 3β position. There was no substantial loss of deuterium in the conversion of (2,2,4,4 ^{2}H)lithocholic acid into the *O*-methyloxime of the 3-oxo derivative. Unlabeled ethanol decreased abundance of monodeuterated lithocholic acid molecules to 21%; when (1,1-^{2}H)ethanol was present the abundance increased to 29%. Excreted 3α-hydroxy-5-cholanoate sulfate had a deuterium excess in 20 atoms % in the 3β position and of 24 atoms % in the C-2 and C-4 positions. It is concluded that different pools of NADPH are used for reduction of the 4,5 double bond and of the 3-oxo group.

5389 TWO DISTINCT PATTERNS OF GLUCOSE INTOLERANCE IN ICTERIC RATS AND RABBITS. RELATIONSHIP TO IMPAIRED LIVER MITOCHONDRIA FUNCTION.

(E.) Yamada, T.; Ida, T.; Yamaoka, Y.; Ozawa, K.; Takasan, H.; Honjo, I. (Kyoto Univ. Fac. Med., Japan). *J. Lab. Clin. Med.* 86(1):38-45, 1975.

The correlation between the degree of glucose tolerance and the degree of liver mitochondrial derangement was studied in animals with liver disease. Rabbits and Wistar rats had the common bile duct doubly ligated close to the liver, and the left branch of the portal vein ligated. P.o. glucose tolerance test was performed after a 15-hr fast in rats subjected to ligation for 3 weeks and rabbits subjected to ligation for 48 hr. Glucose (3 g/kg in rats and 2 g/kg in rabbits) in 20% solution was given intragastrically, and blood samples were taken at intervals up to 6 hr. Insulin tolerance was determined by i.v. injection of insulin (1 U/kg in rats, and 0.2 U/kg in rabbits). Liver mitochondria were assayed for oxygen consumption, phosphorylative efficiency, respiratory carrier content, protein, and respiratory control ratio. In icteric rats, blood glucose peak was reached in 2 hr, in contrast to 1 hr for controls, and was significantly higher (159 mg/dl) than in controls (137 mg/dl). The plasma immunoreactive insulin peak was reached in 1 hr, in contrast to 30 min for controls, and was significantly higher than in controls. In icteric rabbits, blood glucose level increased gradually for 6 hr to a significantly higher level. Plasma immunoreactive insulin response peaked at 3 hr, compared with 30 min for controls, and was significantly higher than in controls. In icteric rats, blood glucose and plasma immunoreactive insulin levels were not significantly different from controls. In icteric rabbits, blood glucose levels at 15 and 30 min after insulin injection were significantly higher than those in controls. In both rats and rabbits with ligated portal veins, phosphorylase/unit of cytochrome a $(+a_3)$ decreased rapidly to 15/sec in 24 hr and remained constant. In rats with bile duct ligation, the activity per unit of $a(+a_3)$ cytochrome fell to 20/sec in 2 weeks and remained constant. In the icteric rabbits, activity rapidly decreased to 10/sec in 24 hr after ligation. Respiratory control ratio, State 3 respiration, and phosphorylase activity/mg protein/min were significantly higher in icteric rats than those with ligated portal veins. Of the icteric rats, 90% lived beyond three weeks, while nearly all the icteric rabbits died within three days. It is concluded that glucose intolerance in icteric rats and rabbits is related to severity of liver mitochondrial derangement.

5390 SPECIFIC DEUTERIUM LABELLING AND COMPUTERIZED GAS CHROMATOGRAPHY-MASS SPECTROMETRY IN STUDIES ON THE METABOLISM IN VIVO OF A STEROID SULPHATE IN THE RAT.

(E.) Baillie, T. A.; Eriksson, H.; Herz, J. E.; Sjovall, J. (Dep. Chem., Karolinska Inst., Stockholm, Sweden). *Eur. J. Biochem.* 55(1): 157-165, 1975.

Specific deuterium labeling and computerized gas chromatography-mass spectrometry were used to study the metabolism of allopregnan-3β-01-20-one sulfate in bile fistula rats and in isolated perfused rat livers. The deuterium-labeled steroid (about 0.5 mg) was dissolved in 50% ethanol and isotonic glucose solution and injected i.v. into male and female Sprague-Dawley rats with bile fistulas. The steroid, again dissolved in ethanol and isotonic glucose, was added to the perfusate 20-100 min after the start of perfusion of isolated livers. The biliary steroids in each case were extracted from the bile samples collected during steroid treatment, purified, and analyzed by gas-liquid chromatography and combined gas chromatography-mass spectrometry. The male rats excreted a-lopregnan-3β-01-20-one sulfate metabolites into the bile more rapidly than did the females, an observation which was correlated with the preferential formation of glucuronide conjugates in the male liver. The major metabolic pathway in the males involved hydrolysis, 2α-hydroxylation, oxidoreduction at C-3, and glucuronide conjugation, to yield 2α,3α-dihydroxy-5α-pregnan-20-one glucuronide as the major metabolite; only traces of the injected steroid sulfate were detected in bile from male rats. In contrast, the injected steroid sulfate was the major steroid excreted in the bile of the female rats; in this case, the primary metabolite was identified as 3β,15β-dihydroxy-5α-pregnan-20-one sulfate. A minor metabolite, 3β,16α-dihydroxy-5α-pregnan-20-one, was found as a monosulfate in the females and as both a disulfate and a glucuronide conjugate in the males. The deuterium content of the sulfated 15β- and 16α-hydroxylated metabolites was consistent with metabolic pathways involving direct hydroxylation of the injected steroid sulfate. Similar results were obtained in the liver perfusion experiments, which indicates that all the observed metabolic reactions took place in the liver. The results demonstrate the advantages associated with the use of stable isotopes in studies of steroid metabolism.

5391 SERUM CALCIUM AND HEPATIC KUPFFER CELL PHAGOCYTOSIS.

(E.) Ryder, Jr., K. W.; Kaplan, J. E.; Saba, T. M. (Albany Med. Coll., N.Y.). *Proc. Soc. Exp. Biol. Med.* 149(1):163-167, 1975.

The effect of experimental alterations of serum calcium levels on opsonin-mediated hepatic phagocytosis was investigated in male Holtzman rats. Serum calcium concentration was altered by the addition of calcium chelators (oxalate, citrate, and EDTA) or by the addition of exogenous calcium. The test colloid used for the phagocytic studies was gelatinized "reticuloendothelial test lipid emulsion"; hepatic phagocytosis was assayed *in vitro* using an isotopic liver slice technique. Upon the addition of oxalate, phagocytosis was depressed in proportion to the amount of oxalate added. At the highest concentration of the chelator (2 μM/ml serum), phagocytosis was 49.6% of control with oxalate, 35.8% of control with citrate, and 48.3% of control with edetic acid. When exogenous calcium was added to serum pretreated with oxalate or citrate, enhancement of phagocytosis occurred with calcium levels up to normal; at calcium levels above normal, there was a significant depressant effect on phagocytosis. The findings suggest that alterations of serum calcium may induce significant changes in reticuloendothelial function which may produce a state of altered host resistance.

5392 LIVER REGENERATION: AN ISOLATION PERFUSION SYSTEM EMPLOYED TO ASSAY HEPATIC ^{3}H-THYMIDINE INCORPORATION. *(E.)*

Sera, Y.; McLeod, J. W.; Koga, Y.; Nicolson, M. O.; Hays, D. M. (Child. Hosp. Los Angeles, Calif.). *Proc. Soc. Exp. Biol. Med.* 149(1):294-298, 1975.

The ability of hepatic cells to incorporate a labeled DNA precursor was studied using an isolation-perfusion apparatus. Male Sprague-Dawley rats were subjected to either a 68% hepatic resection or sham-hepatic mobilization. Isolated, whole normal rat livers were perfused with 2 types of suspension, perfusate that had passed through a regenerating liver and perfusate that had passed through a "sham" operated liver. After the initial 10 min of perfusion, 125 μCi thymidine-me-^{3}H was introduced into the perfusate, and perfusion was continued for 60 min. The livers were then removed and small pieces were fixed for autoradiographic studies; DNA was extracted from the remaining liver. Isolated normal livers perfused with suspension which had been previously circulated through either regenerating or sham-operated livers showed equal and relatively low levels of both tissue specific activity and nuclear labeling. When fresh perfusates were circulated through regenerating livers, nuclear uptake was apparent and specific activity was increased more than 100 times that found in similarly perfused sham-operated livers. No evidence of a factor which can rapidly increase the ^{3}H-thymidine uptake in a perfused normal liver was detected in these studies. The hepatic perfusion system represents a method of demonstrating the capacity for active DNA synthesis in liver cells, employing perfusion as a substitute for i.v. or i.p. injection of labeled compounds in intact animals.

5393 EFFECT OF INTRA-ARTERIAL INFUSION OF VASOPRESSIN ON HEPATIC ARTERY FLOW. *(E.)*

Fingeroth, R. J.; Storer, E. H.; Ramsby, G. R.; Conn, H. O. (VA Hosp., West Haven, Conn.). *Surg. Forum* 24:399-402, 1973.

The possibility of hepatic ischemia developing secondary to decreased hepatic artery blood flow after vasopressin administration was studied in 15 dogs. Noncannulating electromagnetic flow probes were used to monitor blood flow through the hepatic and splenic arteries and portal veins following the intraceliac infusion of 10 U of vasopressin. The preinfusion and postinfusion angiograms of ten patients undergoing therapeutic intraceliac vasopressin infusion were also studied. Upon the arrival of vasopressin in the celiac axis, hepatic artery flow fell to 65% of baseline values, and splenic artery flow fell to 50% of baseline values. Over the next min, the systemic blood pressure rose to 134% of baseline values and the portal vein flow fell to 51% of baseline values. As the portal vein flow decreased, the hepatic artery flow increased, reaching a mean value of 136% of baseline values. This state remained constant throughout vasopressin infusion, with all flows returning to baseline values postinfusion. In the ten human patients, the postvasopressin infusion angiograms showed no change, or showed an actual increase in hepatic artery diameters, while the splenic, gastric, and gastroduodenal arteries showed marked distal vasoconstriction. It is concluded that hepatic artery infusion of vasopressin is not hazardous provided compensatory dilatation occurs as documented by angiography after a brief trial infusion.

5394 COPPER METABOLISM AFTER BILIARY FISTULA, OBSTRUCTION, OR SHAM OPERATION IN RATS. *(E.)*

Owen, C. A., Jr. (Dep. Biochem., Mayo Clin., Rochester, Minn.). *Mayo Clin. Proc.* 50(7):412-415, 1975.

The excretion of copper was studied after biliary obstruction in male Sprague-Dawley rats. The animals were subjected to surgical procedures whereby the bile duct was cannulated and the cannula was threaded out through the skin, the bile duct was doubly ligated and the intervening segment resected, or laparotomy and exposure of the bile duct was followed by simple resuturing of the wound (sham operation). All rats were given vitamin K (0.5 mg) s.c. every other day and i.v. ^{67}Cu (1 μCi) injections. The carrier-free ^{67}Cu appeared rapidly in the bile of the rats with recently-created bile fistulas, maximum excretion occuring within the first 2 hr. However, in animals in which the biliary fistula had been created 3-4 days previously, only one to one-half as much of the isotope appeared in the bile. There was also a small decrease in stable biliary copper in these rats. When the biliary fistula rats were compared over a period of 6 weeks to those with permanent biliary obstructions, both groups exhibited a marked increase in plasma copper and an equally pronounced increase in plasma *p*-phenylenediamine oxidase activity; there was no increase in hepatic copper. Peaks in the blood copper levels were reached within 2 weeks and then slowly diminished. In the sham-operated rats, the copper and enzyme changes paralleled those in the other groups but were much less marked. The results suggest that in inherited copper retention (Wilson's disease) or acquired copper retention (primary biliary cirrhosis), there may be a pathogenic abnormality in the bile which induces copper retention in these diseases. The results also suggest that the absence of bile in the gut alters copper metabolism.

5395 ULTRASTRUCTURAL CHANGES IN RAT HEPATOCYTES FOLLOWING ACUTE METHYL MERCURY INTOXICATION. *(E.)*

Desnoyers, P. A.; Chang, L. W. (Dep. Pathol., Univ. Wisconsin, Madison). *Environ. Res.* 9(3):224-239, 1975.

The pathological and morphological effects of acute and chronic methyl mercury intoxication on the rat liver were studied. Male Sprague-Dawley rats were given up to four consecutive daily s.c. injections of methylmercuric chloride at a dosage of 10 mg/kg. The animals were fasted for 24 hr before sacrifice and were killed 1, 5, 10, 24, 48, or 96 hr after the beginning of methyl mercury treatment. Ultrathin sections of the livers were examined by electron microscopy. No neurological symptoms were observed in any of the animals. Grossly, the livers appeared atrophied and adhesion of the liver to the visceral organs occured after the second injection. Ultrastructural changes in the hepatocytes were observed as early as 5 hr after the initial mercury injection; these included a wavy appearance of the mitochondrial membrane, dilatation of the rough endoplasmic reticulum, and occasional accumulation of electron-dense granules (liposomes) near the bile canaliculi. After 24 hr, there was a general depletion of glycogen and focal amorphous areas appeared in the cytoplasm of many cells. Large areas of cytoplasmic degradation were also observed and cellular materials were frequently observed to be extruded into the hepatic sinusoids. Extensive matrical swelling of the mitochondria with concomitant loss of the mitochondrial granules were observed after 2 days; breakage of the outer mitochondrial limiting membranes, loss of the mitochondrial cristae, and an increase in the number of lysosomes were also noted at this time. Sequestration of cytoplasmic organelles, many of them degraded, within the hepatocytes to form large membrane-limited cytosegresomes was observed after 4 days. Degenerated organelles, Kupffer cells and cellular debris were frequently found extruded into the hepatic sinusoids and moderate fatty changes in some hepatocytes were observed. The data indicate that the most extensive degenerative changes in the liver occur after 2 days of methylmercury administration.

5396 TECHNETIUM ^{99m}-PYRIDOXYLIDENEGLUTAMATE: A NEW HEPATOBILIARY RADIOPHARMACEUTICAL. I. EXPERIMENTAL ASPECTS.

(E.) Baker, R. J.; Bellen, J. C.; Ronai, P. M. (Inst. Med. Vet. Sci., Adelaide, South Australia). *J. Nucl. Med.* 16(8):720-727, 1975.

The electrophoretic behavior, *in vivo* distribution, toxicity, and reabsorption of technetium-99m-pyridoxylideneglutamate (^{99m}Tc-PG) were studied in balb/c mice and female rats to determine the potential of this radiopharmaceutical for the scintigraphic diagnosis of biliary tract disorders in man. Labeling of pyridoxal and the pyridoxylidene derivative of glutamic acid with ^{99m}Tc was achieved by a simple autoclaving procedure, after which the autoclaved reaction mixture was examined using electrophoresis on cellulose acetate membrane. The compound (75 to 500 μCi) was injected i.v. into balb/c mice and dogs, and its biliary and urinary excretion and tissue distribution were studied; the acute toxicity of PG was also determined in mice, and its antigenicity was studied in guinea pigs. In the reabsorption experiments, radioactive bile from a donor rat given i.v. ^{99m}Tc-PG was injected into the duodenum of a recipient rat and the radioactivity in the blood, bladder, bile and urine was determined at 15-min intervals. Both scintigraphic and quantitative distribution studies showed that ^{99m}Tc-PG passed rapidly through the mouse liver with progressive accumulation in the gallbladder, allowing visualization of this organ within 10 min of injection. Within 30 min, over 40% of the injected dose was excreted into the intestine with an equivalent amount appearing in the urine; renal activity was low. Scintigraphic studies in dogs yielded similar results. The LD_{50} of this compound in mice was about 1,400 mg/kg, but there were no apparent toxic reactions or histological changes noted after the cumulative administration of 2,820 mg/kg in ten equal doses. The preparation was sterile, pyrogen-free, and did not produce an antigen reaction in guinea pigs. In the reabsorption experiments, the radioactivity appearing in the blood of the recipient at 2 hr reached 0.02% of the dose/ml; no activity was observed in the bladder at this time. It is concluded that ^{99m}Tc-PG would be a suitable agent of low toxicity for use in humans for the investigation of biliary tract disorders.

5397 ENDOTOXIN-INDUCED LIVER NECROSIS AND INTRAVASCULAR COAGULATION IN RATS ENHANCED BY PORTACAVAL COLLATERAL CIRCULATION.

(E.) Liehr, H.; Grun, M.; Thiel, H.; Burnswig, D.; Rasenack, U. (Dep. Med., Univ. Wurzburg, Germany). *Gut* 16(6):429-436, 1975.

The effects of i.v. endotoxin on the hepatic and systemic circulation and on the coagulation system were evaluated in normal, non-fasted FW 49 rats and in rats with experimental portal hypertension or portacaval anastomosis. Endotoxin (1.5 mg/kg) was injected into the penile vein and the cardiac output and hepatic blood flow were measured. Coagulation factors II, V, VII, and X were also determined, as were the fibrinogen level and platelet count, the activities of SGOT and SGPT, phagocytic activity, and the serum bilirubin and blood sugar concentrations. Specimens of liver, lungs and kidney were examined histologically. In the normal rats, endotoxin administration led to a prompt increase in the serum transaminase activity and to a hyperdynamic circulation with a consequent increase in the total hepatic blood flow. Six hr later, the hepatic artery dilated with a subsequent hepatic arterial hyperperfusion. The coagulation system was also affected, with signs of consumption coagulopathy. Endotoxin treatment resulted in acute liver necrosis within 12-15 hr in the rats with portal hypertension and portacaval collaterals as well as in those with portacaval anastomosis. The hepatic artery became overdilated with a cardiac output fraction of 25%, compared to a normal value of 5.5%. Blood extravasates and thrombi, rich in fibrin, were detected in the liver. Hypocoagulation, greatly elevated transaminase activity, and greatly reduced blood sugar levels were also observed. It is suggested that the exaggerated endotoxin effect in these rats was due to an impairment in the clearance function of the reticuloendothelial system, probably as a consequence of portacaval collateral circulation. It is concluded that endotoxins damage the liver, even in normal organisms, that they are potent inducers of acute liver necrosis if the reticuloendothelial system is altered, and that they should be considered in the pathogenesis of acute and chronic liver diseases.

5398 MORPHOLOGICAL FINDINGS IN SWINE LIVER HOMOGRAFTS AFTER ORTHOTOPIC AND AUXILIARY HETEROTOPIC TRANSPLANTATION.

(Ger.) Seidler, D.; Trautwein, G.; Lauchart, W.; Bockhorn, H. (Veterinary Med. Coll., Hannover, Germany). *Z. Immunitaetsforsch.* 148(1):1-15, 1974.

Morphological and immunohistochemical studies were performed on the livers of donor and recipient swine before and after transplantation and after the death of the recipient, 2 days to 1.5 yr later. Orthotopic transplants were performed on 20 swine and heterotopic auxiliary transplants on ten. No immunosuppressive agents were employed. Gross examination of the livers of swine that died within 5 days after surgery revealed hepatomegaly and changes in blood supply. One animal had a completely necrotic left lobe with no signs of a thrombus in branches of the hepatic artery or portal vein supplying this area. In swine surviving 5 days to 3 weeks, boundaries between the lobes and the periportal fields were more clearly defined than in normal animals; almost half of the swine had hepatomegaly. Rejection was manifested by parenchymal bleeding and small areas of necrosis which gave cut sections a variegated appearance. Of the swine receiving orthotopic transplants, 2 developed total and 2 others partial stenosis of the common bile duct near the suture line and intrahepatic cholestasis. In swine surviving longer than 3 weeks, periportal fields became wider, the hepatic capsule was thickened and fibrotic, and lobular architecture was lost. Nonspecific histological changes found immediately after surgery included marked dilatation of central veins and sinusoids, centrilobular hepatocyte dissociation, and Kupffer cell activation. Large centrilobular vacuoles, nuclear degeneration, isolated cellular necrosis, and edema of periportal tissue were observed in swine that died within 5 days after surgery. In animals that survived longer, lymphocyte infiltrations, isolated cellular necrosis, and fibrotic widening of the boundaries between lobules were detected. Other nonspecific changes included leukocyte infiltration of the bile ducts and bile duct proliferation which developed in association with stenosis and partial stenosis of the common bile duct. Morphological changes resulting from immunological differences between the donor and recipient varied with the survival time and the intensity of the immune reaction; no appreciable differences were found between orthotopic and auxiliary heterotopic transplants. These changes consisted of lymphocyte infiltration beginning in the portal triads and eventually resulting in fibrosis. The fluorescent antibody technique failed to demonstrate that humoral antibodies participate in the rejection reaction.

5399 IS GLUCOSE THE PORTAL HEPATOTROPHIC SUBSTANCE? *(E.)* Mooney, C. S.; Griffen, W. O., Jr. (Univ. Kentucky Med. Cent., Lexington). *Surg. Forum* 24:379-381, 1973.

The possible role of glucose in preventing liver shrinkage following substitution of systemic for portal venous blood was studied in adult dogs. Partial portacaval transposition was performed in each animal so that the right hepatic lobe received splanchnic venous blood while the left lobe received systemic venous blood. For five days following surgery, the dogs were given commercially available horse meat once daily and water *ad libitum*. For five hr after eating, half of the dogs received 500 ml of saline at a rate of 100 ml/hr i.v. in a hind limb; the others received a similar amount of 5% dextrose in saline. There were no significant alterations in the SGOT, bilirubin, or alkaline phosphatase values after surgery in any of the animals, and all maintained their appetite and weight throughout the study. At 60 days after surgery, the right liver lobes appeared normal in all dogs and the left lobes appeared normal in the glucose group. The left lobes in the saline group were paler, significantly smaller, and firmer than normal, weighing on an average only 249 g compared to 410 g in the glucose group. Histologically, the portions of liver receiving splanchnic blood were normal; the left lobes in the glucose group showed some mononuclear infiltration at the portal triads, and the left lobes of the saline group showed increased fibrous tissue and small, irregular, darker hepatocytes. The results support the hypothesis that depriving the liver of portal venous inflow leads to a "starvation" sequence; that portion of the liver which does not receive postprandial glucose-laden blood cannot metabolize and store glycogen and therefore undergoes shrinkage. The role of insulin in this process appears to be less critical than exposure of the hepatocytes to glucose.

5400 LIVER, BILIARY SYSTEM, AND GASTROINTESTINAL MUCOSA: SITE OF ORIGIN OF THE HEPATOTROPHIC PORTAL BLOOD FACTOR INVOLVED IN LIVER REGENERATION. *(E.)* Sgro, J. C.; Charters, A. C.; Chandler, J. G.; Grambort, D. E.; Orloff, M. J. (Univ. California, San Diego Sch. Med., La Jolla). *Surg. Forum* 24:377-379, 1973.

Liver regeneration was examined in male Lewis rats after selective ablation of the splanchnic organs to study the site of origin of the hepatotrophic portal blood factor responsible for liver regeneration. All animals were starved for 48 hr then subjected to 70% hepatectomy. In addition, some were subjected to small-intestine resection; resection of the spleen, stomach, duodenum, and pancreas; resection of the stomach, spleen, and duodenum; pancreatectomy; or gastrectomy. Biliary and gastrointestinal continuity were reestablished by anastomoses. All animals were killed 24 hr after surgery, having been injected i.p. with tritiated thymidine (250 µc) 30 min prior to sacrifice. The mitotic index, labeled nuclei, and DNA uptake of ^{3}H-thymidine were examined in the remnant liver. Marked regenerative activity of the residual liver segment was evident in the animals which had undergone hepatectomy, hepatectomy plus small-intestine resection, and hepatectomy plus gastrectomy, the magnitude of the response being reduced in the latter 2 groups compared with the first group. No regenerative activity was noted after hepatectomy plus removal of the stomach, spleen, pancreas, and duodenum, or after hepatectomy plus removal of the stomach and duodenum or the pancreas alone. The data indicate that the hepatotrophic portal blood factor is not a nutrient substance absorbed from the gastrointestinal tract. They also suggest that the site of origin of this factor is not the small intestine or stomach, although the pancreas and/or duodenum may prove to be the source of this humoral factor.

5401 ANIMAL MODEL OF HUMAN DISEASE: CHRONIC BILIARY OBSTRUCTION. *(E.)* Stanley, N. F.; Joske, R. A. (Dep. Microbiol., Univ. West. Australia, Nedlands). *Am. J. Pathol.* 80(1):185-187, 1975.

A murine model is described which might be used to study the clinical and pathologic features of chronic biliary obstruction in man. Nonbacterial infections producing chronic biliary obstruction in humans are at present an enigma. Obstruction may result from a viral hepatitis-induced cholestatic syndrome, fibrous strictures at the lower end of the common bile duct in the absence of either pancreatitis or cholelithiasis, or from viral infections which produce biliary obstructions secondary to viral pancreatitis. The i.p. inoculation of weanling mice with massive doses of reovirus Type 3 resulted in a 40% incidence of chronic obstructive jaundice within 3 or more weeks. Jaundice resulted from the obstruction of the common bile duct at the duodenal end following denudation of the bile duct mucosa. One week after inoculation, reovirus was observed replicating in the bile duct mucosal cells, but no infective virus could be detected at 3 weeks. Virions passed both the sinusoidal and hepatic layers before reaching the common bile duct, the cells lining its lumen being invaded when the viral titer in the duct became high enough. The cellular necrosis and inflammatory response to virus invasion were followed by fibrosis in the terminal portion of the common bile duct. The subsequent stricture formation and obstruction of flow in the common bile duct were responsible for the hepatic and pancreatic lesions seen in the later stages of the disease. This model suggest that some cases of biliary obstruction at the ampulla of Vater might occur following viral choledochitis. A combined clinical and epidemiologic approach with attempted virus isolation from blood and feces, as well as viral and electron microscopic study of possible surgical specimens, might aid in the study of chronic biliary obstruction in man.

5402 RAPID UPTAKE BY LIVER SINUSOIDAL CELLS OF SERUM ALBUMIN MODIFIED WITH RETENTION OF ITS COMPACT CONFORMATION. *(E.)* Buys, C. H. C. M.; De Jong, A. S. H.; Bouma, J. M. W.; Gruber, M. (Biochem. Lab., Univ. Groningen, The Netherlands). *Biochim. Biophys. Acta* 392(1):95-100, 1975.

The conformation and blood clearance of nitroguanidinated albumin were studied using nitroguanidinated bovine serum albumin and native albumin, labeled with ^{125}I and injected into rats. The radioactivity in the plasma and liver were determined in the first hours after injection, and the subcellular localization of the protein was compared with that of the lysosomal enzymes acid phosphatase and cathepsin D. The nitroguanidination-induced changes in the albumin molecule were studied by gel filtration on Sephadex G-200 and by chemical characterization of native, nitroguanidinated, and formaldehyde-treated albumin. Nitroguanidination resulted in replacement of the positively-charged amino groups on the albumin molecule by neutral nitroguanido groups. However, there was no significant folding of the modified albumin molecule and the number of reducible disulfide groups was not appreciably increased. Like formaldehyde-denatured albumin, but in contrast to the native protein, the nitroguanidinated derivative was rapidly cleared from the blood *in vivo* and was taken up in the lysosomes of the liver sinusoidal cells. It is concluded that extensive denaturation is no prerequisite for the uptake of albumin derivatives by the liver sinusoidal cells. It is further suggested that the nitroguanidinated protein, in contrast to native albumin, is bound on membrane receptors of these cells. The nitroguanidine groups themselves may be bound on these receptors, but it seems equally possible that binding on the receptors is the result of a net increase in the negative charge of the albumin molecule or of local conformational changes in the protein.

5403 EFFECT OF DECREASED GALLBLADDER STIMULATION ON ENTEROHEPATIC CYCLING AND KINETICS OF BILE ACIDS. *(E.)* Hepner, G. W. (Milton S. Hershey Med. Cent., Pennsylvania State Univ., Hershey). *Gastroenterology* 68(6):1574-1581, 1975.

The effect of dietary protein and fat on the rate of enterohepatic recycling and bile acid kinetics was studied in patients with cholesterol cholelithiasis, in cholecystectomized patients and in control subjects. The effect on enterohepatic cycling was assessed indirectly by comparing the 24-hr output of breath $^{14}CO_2$ after administration of 2 μCi of cholyl (1-^{14}C)glycine during two periods: a control period when three meals containing protein and fat were eaten daily; and a diet period, when protein and fat were excluded from the diet for a period of 72 hr. Bile acid kinetics after the p.o. administration of (2,4-^{3}H)cholic acid and (24-^{14}C)chenodeoxycholic acid were measured in six healthy subjects during a control period and again, not less than 4 months later during the fourth week of a dietary program in which one meal containing fat and protein was consumed every other day. In the first study, breath $^{14}CO_2$ output was not altered by diet in the cholecystectomy patients. In the healthy subjects and in the patients with cholesterol cholelithiasis, however, the breath $^{14}CO_2$ output fell by about 50%; this indicated that decreased endogenous cholecystokinin-pancreozymin stimulation had reduced but not eliminated enterohepatic recycling in these subjects. In the second study, the pool size of cholic and chenodeoxycholic acid in the bile rose significantly during the low fat and protein diet; the total bile acid pool size also decreased. The daily fractional turnover rate of both primary bile acids fell significantly during the diet, but their rate of synthesis was not significantly changed. It is concluded that significant enterohepatic circulation of bile acids occurs even in the absence of dietary stimuli for gallbladder contraction and that diet may significantly affect bile acid pool size and fractional turnover, while bile acid synthesis remains essentially unaffected.

5404 HEPATIC BLOOD FLOW AND OXYGEN CONSUMPTION IN STARVATION, SEPSIS AND SEPTIC SHOCK.

(E.) Imamura, M.; Clowes, G. H. A., Jr. (Harvard Med. Sch., Boston, Mass.). *Surg. Gynecol. Obstet.* 141(1):27-34, 1975.

The normal pattern of hepatic circulation and oxygen consumption in the fasted state was compared with that observed during sepsis. Sepsis was induced in male and female pigs by cecal ligation, which produced a fulminating i.p. abscess containing coliform organisms. Prior to the induction of sepsis, the pigs were fasted for 4 days, thermodilution catheters being inserted into the portal vein and inferior vena cava on the third day; silastic tubes were also inserted into the external jugular vein, the common carotid artery, and the left common hepatic vein. On the fourth day, measurements of cardiac output, arterial blood pressure, heart rate, inferior vena cava pressure, portal venous pressure, total hepatic blood flow, portal blood flow, and body weight were carried out in the fully conscious animals. The cecum was then ligated and after 3 more days, these measurements were repeated. In the septic high output state (in which the pig showed a higher cardiac output in the septic state than in the normal fasted state), the average cardiac output was 155% of that during normal fasting, the hepatic arterial flow increased 96%, the portal flow decreased 19%, the total hepatic flow increased 14%, the ratio of total hepatic blood flow to cardiac output decreased from 42% (normal fasted state) to 30%, and the total hepatic oxygen consumption increased 26%. In the low output state (in which the pig showed a lower cardiac output in the septic state than in the normal fasted state), the hepatic arterial flow decreased 74%, the portal flow decreased 23%, the total hepatic flow decreased 38%, the cardiac output decreased 38%, the ratio of total hepatic blood flow to cardiac output was 31%, total hepatic oxygen consumption decreased 29.1%, and splanchnic oxygen consumption decreased 22%. Only one of 11 pigs in the septic high output group died during the 3 days of observation, while 11 of 16 in the septic low output group died during this period. The remarkable difference in survival between the septic high and low output groups appeared to be largely due to the significant decrease in hepatic arterial flow and oxygen supply to the liver in the low output state.

5405 FORMATION OF COLONIES IN SOFT AGAR MEDIUM BY REGENERATING LIVER CELLS.

(E.) Hays, D. M.; Sera, Y.; Koga, Y.; Hays, E. F. (Univ. South. California Sch. Med., Los Angeles). *Proc. Soc. Exp. Biol. Med.* 148(2):596-599, 1975.

The effect of serum factors, which have been shown to be stimulatory for marrow cells, on the colony-forming properties of cells from regenerating liver tissue was studied. Regenerating liver tissue was obtained from male Fischer rats and male C57BL/6 mice; this tissue was minced, trypsin-dispersed and cultured in soft agar medium. Designated cultures were supplemented with 40 µl of normal mouse serum (NMS), endotoxin mouse serum (EMS, obtained after the i.v. inoculation of endotoxin), or endotoxin rat serum (ERS). Normal liver cells, bone marrow cells from mature mice, and fetal rat and mouse liver cells were similarly treated. In the rat cell cultures, the greatest number of colonies was obtained from liver tissue obtained 48 hr after resection, the number of colonies being increased by a larger cell inoculum and being inversely related to the animal's weight. The effects of added EMS or ERS and the substitution of 15% human or rat serum for the normal 15% fetal calf serum additive were negligible. In the mouse cell cultures, colonies were obtained only from tissue obtained 72 to 168 hr postresection. These colonies were larger than those formed from regenerating rat liver. Only regeneration and fetal mouse liver formed a significant number of colonies in the absence of EMS or NMS; in the presence of these serum factors, the greatest number of colonies was formed by bone marrow, with fetal and regenerating liver yielding smaller and similar numbers of colonies. The cellular composition of these colonies was clearly distinguishable as granulocytic, granulocytic-macrophage, or macrophage. An additional colony type seen only in regenerating mouse liver cultures contained sheets of apparently epitheloid cells. The cell type of the rat liver colonies could not be clearly identified. The results indicate that regenerating mouse liver contains cells which can form granulocyte or macrophage colonies in soft agar in the presence of NMS or EMS. It appears that there is a nonhematopoietic cell population in regenerating liver that can also form colonies.

5406 ACTIVITIES OF HEPATIC MICROSOMAL ELECTRON TRANSPORT SYSTEM IN PROLONGED ETHANOL-TREATED RATS.

(E.) Nakanishi, S.; Shiohara, E.; Tsukada, M.; Kinoshita, G. (Fac. Med., Shinshu Univ., Matsumoto, Japan). *Jpn. J. Pharmacol.* 25(1):71-73, 1975.

The activities of the main components of the hepatic microsomal electron transport system were studied in rats given prolonged ethanol treatment in the presence of aminopyrine or aniline. Wistar rats were given ethanol p.o. *ad libitum*, fasted 12 hr and sacrificed. Cytochrome P-450 and b_5 content, cytochrome P-450 reductase activity, cytochrome C reductase and NADPH oxidase activity, and microsomal protein content were determined. Cytochrome P-450 reductase, cytochrome C reductase, and NADPH oxidase activities increased significantly in the absence of drug substrate, compared to controls. Cytochrome P-450 reductase and cytochrome C reductase activities increased significantly in the presence of 3 mM of aminopyrine as compared to controls. With cytochrome P-450 reductase, there was no difference in the rate of reduction of the cytochrome in the presence of aminopyrine. The rate of cytochrome P-450 reduction was similar to that of controls in the presence of 2 mM of aniline. NADPH cytochrome C reductase activity was significantly higher than that of controls. The inhibitory effect of aniline was higher in the treated than in the control group. It is concluded that part of the cytochrome P-450 fraction increased by ethanol treatment is qualitatively different than that of controls.

5407 SYNCHRONIZED LIVER CELLS: A NEW TOOL FOR ANALYSIS OF CELL-CYCLE DEPENDENT CARCINOGEN-BINDING TO DNA IN VIVO. *(E.)*

Rabes, H. M.; Iseler, G.; Tuczek, H. V.; Kerler, R. (Pathol. Inst., Univ. Munich, Germany). *Experientia* 31(6):686-687, 1975.

A qualitative comparison was made between the degree of DNA alkylation prior to, during and after DNA replication *in vivo*. Four groups of six Wistar rats each were 2/3 hepatectomized and given i.p. N,N-di(^{14}C)methyl-nitrosamine (0.18 Ci/mM), and ^{3}H-thymidine (0.8 Ci/g; 5 Ci/mM). The first group was partially hepatectomized prior to the injections. The second group was given the injections during continuous infusion of hydroxyurea, 28 hr after hepatectomy. The third group was given injections 43 hr after partial hepatectomy and four hr after stopping a hydroxyurea infusion (14 to 39 hr after hepatectomy); the fourth group was given the injections 47 hr after hepatectomy, and eight hr after stopping the infusion. Radioactivity from the two labels was measured separately by liquid scintillation spectrometry. The specific activity of DNA from the ^{3}H-thymidine was low in the G_1 phase, and also during hydroxyurea-induced DNA synthesis inhibition at 28 hr after hepatectomy. DNA synthesis showed a high rate 4 hr after removal of hydroxyurea blockage; it was reduced again by 8 hr after, when the cells were in G_2. The specific activity of ^{14}C in the G_1 phase and during hydroxyurea inhibition was low and without significant difference. DNA incorporation of ^{14}C increased significantly 4 hr after removal of hydroxyurea blockage. Specific activity remained at increased levels, even at 8 hr after, when the cells were in G_2. It is concluded that ^{14}C uptake varies with cell cycle phase, implying differing sensitivity to carcinogen-induced base alkylation.

5408 MICROFILAMENT DYSFUNCTION AS A POSSIBLE CAUSE OF INTRAHEPATIC CHOLESTASIS. *(E.)*

Phillips, M. J.; Oda, M.; Mak, E.; Fisher, M. M.; Jeejeebhoy, K. N. (Toronto Gen. Hosp., Canada). *Gastroenterology* 69(1):48-58, 1975.

The possible function of pericanalicular microfilaments in the regulation of bile canalicular structure and function was investigated. Cultured rat hepatocytes, isolated perfused rat liver, and *in vivo* perfused rat liver were used as models. The cells were cultured with either cytochalasin B (20 μg/ml), 0.8% dimethylsulfoxide (DMSO) or phosphate buffer only (final concentration 0.0015 M). Samples were taken for electron microscopy at 1, 3, and 6 hr of incubation. Isolated liver was perfused for two hr, then 100 to 150 μg/ml of cytochalasin B and 0.2% DMSO were added to the perfusate. Bile was collected from the common duct and the volume was recorded hourly. Biopsies were taken 30 min, and 1, 2 and 3 hr after addition of the drug. In the *in vivo* experiment, bile flow was measured by common bile duct cannula for two hr. The liver was then perfused with 0.9% NaCl containing 100 μg/ml of cytochalasin B and 0.2% DMSO for one hr. Controls were given the NaCl with DMSO only. Biopsies were taken at 1, 2, and 3 hr after the start of perfusion. About 20-30% of the cultured hepatocytes were paired; they were joined by junctional complexes contiguous with the canaliculi. Light microscopy showed barely visible canicular luminal spaces in the controls, but widely dilated luminal spaces in the treated cells within 3-6 hr. Electron microscopy showed that the numbers of canalicular microvilli decreased steadily after 1 hr of treatment. In the isolated liver, light microscopy showed canalicular dilation, sinusoidal congestion, and fine hepatocytic vacuolarization. Electron microscopy 30 min after treatment showed dilated canaliculi, mostly in the periportal and midzonal regions, with microvillar loss. The pericanalicular ectoplasm was granular and amorphous. After 2 to 3 hr, the changes were panlobular. The cytoplasmic vacuoles contained mostly electron lucent material; the Golgi bodies were prominent. The overall cytoarchitecture was retained. Bile flow decreased over 75% after perfusion of a 100 μg/ml dose of the drug, and was virtually arrested after the 150 μg/ml dose. The *in vivo* liver did not show the cytoplasmic vacuoles and congestion of the isolated liver. Dilation of the canaliculi coincided with significant bile flow reduction. Microvilli were reduced, and autophagic vacuoles containing fibriliar and/or electron-dense material were seen in the panicanalicular area. One hr after treatment, bile flow was reduced 50% and nearly or completely arrested after 2 hr. It is concluded that the microfilaments maintain the canaliculi in a contracted or partially contracted state, and that their disruption is linked to bile flow reduction by an unknown mechanism.

5409 PLASMA DISAPPEARANCE OF RADIOACTIVITY AFTER INTRAVENOUS INJECTION OF LABELED BILE ACIDS IN MAN. *(E.)*

Cowen, A. E.; Korman, M. G.; Hofmann, A. F.; Thomas, P. J. (Mayo Clin., Rochester, Minn.). *Gastroenterology* 68(6):1567-1573, 1975.

The kinetics of the disappearance of free and conjugated bile acids from plasma were studied. Each of six healthy volunteers received i.v. six bile acids (cholic and chenodeoxycholic acids and their glycine and taurine conjugates) in random order. The dose was 10 μCi for ^{14}C-labeled and 25 μCi for the ^{3}H-labeled bile acids. Blood samples were taken from the opposite antecubital vein to the point of injection at 2, 4, 6, 8, 10, 12, 15, 20, 30, 45, 60, 75, 90, 105, and 120 min after injection. The serum was separated and radioactivity was determined by liquid scintillation spectrometry. Subjects fasted throughout the experiment. Every primary bile acid, conjugated or unconjugated, had a biexponential plasma disappearance curve, indicating rapid disappearance. The half-life of the second component of the curve was about five times that of the first component, and they were highly correlated. The disappearance rates of cholylglycine and cholyltaurine were identical to each other, and were significantly faster than those of chenylglycine and chenyltaurine. For cholic and chenic acids, disappearance of the conjugated form was consistently faster than that of the unconjugated form. Dehydrocholyltaurine disappeared more slowly than any other acid; the half-life for the second exponential was 10 times that of the first. Cholic acid, conjugated or not, showed considerably less protein binding in the serum than unconjugated chenodeoxycholic acid, deoxycholic acid or chenodeoxycholic conjugates. Differences in fractions bound to serum protein of cholic acid (91.0%), cholylglycine (85.6%) and cholyltaurine (82.8%) were statistically significant. It is concluded that the primary bile acids, conjugated or unconjugated, rapidly disappear from plasma in a biexponential fashion.

5410 REDUCED BILE FLOW IN RATS DURING SULFOBROMOPHTHALEIN INFUSION. *(E.)* Schulze, P. J.; Czok, G. (Pharmacol. Inst., Univ. Hamburg, Germany). *Toxicol. Appl. Pharmacol.* 32(2):213-224, 1975.

Male urethane-anesthetized Wistar rats with biliary fistulas were infused i.v. with sulfobromophthalein (BSP), or BSP-glutathione conjugate (BSP-GSH) (594 nM/100 g/min) for 100 min. With BSP infusion, the bile flow increased for 25 min and subsequently fell almost linearly. Biliary excretion of BSP-GSH correlated with the bile flow, whereas the hepatic concentration of this metabolite rose during infusion. The concentration of unconjugated BSP also increased in the liver. On the other hand, the infusion of BSP-GSH resulted in a long-lasting choleresis accompanied by high biliary concentrations of BSP-GSH without a concurrent increase in the concentration of BSP-GSH in the liver. The data indicate that during infusion of BSP, the biliary excretion of BSP-GSH is impaired after a peak at 30 min, although its hepatic content rises continuously to 10 μM/100 g body weight or 2.63 μM/g of liver, resp., after 100 min of infusion. The decrease in excretion of BSP-GSH was not due to the limited transport capacity for this metabolite, as a much higher rate of excretion was observed during BSP-GSH infusion. It is concluded that with the infusion of BSP the impaired biliary excretion of BSP-GSH and its increase in the liver are due to the presence of unconjugated BSP in the liver. It is suggested that the conjugation with glutathione may be the rate-limiting step in the biliary excretion of BSP.

5411 PHENOBARBITOL-ENHANCED BILIARY EXCRETION OF ADMINISTERED UNCONJUGATED AND CONJUGATED SULFOBROMOPHTHALEIN (BSP) IN THE RAT. *(E.)* Whelan, G.; Combes, B. (Univ. Texas Southwest. Med. Sch., Dallas). *Biochem. Pharmacol.* 24(13/14):1283-1286, 1975.

The mechanism by which phenobarbitol enhances biliary excretion of sulfobromophthalein (BSP) was studied in Sprague-Dawley rats given sodium phenobarbitol s.c. daily for seven days (7.5 mg/100 mg). Twenty-four hr after the last injection, the common bile duct was cannulized and either unconjugated BSP or synthetic BSP-glutathione was given i.v. (18 μM or 30 μM, resp./100g). Bile was collected 10 min prior to BSP injection and for four consecutive 10 min periods. A blood sample was taken from the aorta at the end of this time, and the liver was removed and weighed. BSP concentration in the bile was determined by spectrophotometry. Bile was also analyzed by descending chromatography on filter paper. Phenobarbitol-treated rats had a marked increase in liver size. Maximum dye excretion in controls after injection of unconjugated BSP was 1.34 μM/100 g/10 min. Phenobarbitol pretreatment significantly raised this to 2.06 μM/100 g/10 min. The rise was accompanied by a bile flow increase from 0.057 to 0.106 ml/100 g/10 min. Phenobarbitol did not affect maximal BSP bile concentration. Chromatography showed 56.8% of the excreted dye was conjugated in the controls and 77.7% in the treated group. Unconjugated dye excretion was not affected. Maximal excretion rates of the conjugated form were higher in the treated group (4.10 μM/100 g/10 min) than in controls (2.71 μM/100 g/10 min). The treated group also showed a rise in bile volume from 0.073 to 0.088 ml/100 g/10 min before conjugated BSP injection. Biliary BSP concentration was higher in rats given conjugated than unconjugated BSP, and was comparable in treated and control rats given conjugated BSP. It is concluded that phenobarbitol enhances BSP excretion by increasing transport of the conjugated form from hepatocytes to bile, and by increasing the rate of its intrahepatic metabolism.

5412 THE ACCUMULATION OF ASPARTATE IN THE PRESENCE OF ETHANOL IN RAT LIVER. *(E.)* Stubbs, M.; Krebs, H. A. (Radcliffe Infirm., Oxford, England). *Biochem. J.* 150(1):41-45, 1975.

The ability of ethanol to cause accumulation of aspartate in rat liver in the presence of excess nitrogen was investigated. Hepatocytes from Wistar rats were isolated and put into suspension; in some cases the cytosolic and mitochondrial components were separated and labeled with markers. The cell suspension was analyzed for glucose, lactate, pyruvate, aspartate, glutamate, alanine, NH_4^+, urea, glutamine, malate, and 2-oxoglutarate content. Ethanol had no effect on aspartate yield in the suspension; it caused an increase in perfused liver. Of the total nitrogen, 17.5% appeared as NH_4^+ in suspension, as compared to 64% in perfused liver. Addition of 1.5 U/flask of urease to the hepatocyte suspension caused a 7-fold increase in aspartate formation on addition of ethanol, indicating that aspartate formation was dependent on NH_4^+ concentration. In the presence of 10 mM of lactate and 10 mM of NH_4Cl, ethanol caused a 22-fold increase in aspartate concentration, and inhibited glucose synthesis by 73%. Ethanol did not affect the amount of NH_4^+ removal, but increased the amount of NH_4^+ converted to aspartate and glutamate, and decreased the amount converted to urea. There was no increase in yields of aspartate and glutamate with or without ethanol, lactate or NH_4Cl. Addition of ornithine increased urea synthesis with or without the presence of ethanol, and abolished aspartate accumulation. It also depressed glucose synthesis from lactate and NH_4Cl, but ethanol partially overcame this depression. When the cells were fractionated, ethanol increased the aspartate yield 10-fold in the cytosol fraction, but did not affect the mitochondrial fraction. It also increased the glutamate content by 1.9 times and 3.7 times in these fractions, resp. The 2-oxoglutarate content was halved by ethanol in the cytosol, but was unaffected in the mitochondria. It is concluded that accumulation of aspartate in the presence of ethanol depends on high concentrations of NH_4^+.

5413 BIOCHEMICAL STUDIES ON THE EFFECT OF A DEPROTEINIZED BLOOD DERIVATIVE ON THE RECOVERY OF RAT LIVER AFTER HEMORRHAGIC SHOCK LASTING 60 MINUTES.

(Ger.) Wolff, R. (Steglitz Clin., Free Univ., Berlin, Germany). *Arzneim. Forsch.* 25(3):388-392, 1975.

The effect of Actihaemyl, a deproteinized extract of calf blood, was tested for its effect on hepatic anoxia caused by hemorrhagic shock. Ether-anesthetized male Wistar rats were bled until their average blood pressure had decreased to 40 mm Hg. After 60 min, their blood was retransfused along with Actihaemyl (5 ml/kg) or placebo (3.51% NaCl solution). Rats were sacrificed 30-120 min after retransfusion, and their livers were removed and homogenized. During shock significant increases occurred in lactate β-hydroxybutyrate contents with decreases in pyruvate values. Anoxia was characterized by an increase in the lactate/pyruvate ratio and a decrease in the ATP/ADP ratio. The glycogen content of the liver decreased to extremely low values. The concentrations of all metabolites studied, with the exception of ADP and acetoacetate, depended on the recovery time after hemorrhagic shock in both rats treated with Actihaemyl and in the controls. In treated rats lactate and β-hydroxybutyrate contents decreased more rapidly than in controls so that the lactate/pyruvate and β-hydroxybutyrate/acetoacetate ratios were decreased. These findings suggest that Actihaemyl increases O_2 uptake in the liver following hemorrhagic shock.

5414 THE EFFECT OF ALCOHOL ON LIPID METABOLISM IN THE ISOLATED PERFUSED RAT LIVER.

(Ger.) Ast, E.; Durr, C.; Bauer, E.; Papenberg, J. (Med. Clin., Univ. Heidelberg, Germany). *Verh. Dtsch. Ges. Inn. Med.* 80:479-481, 1974.

The synthesis and secretion of lipoproteins were studied in the presence and absence of ethanol in isolated perfused livers from nonfasted rats. Livers were perfused for 4 hr with a medium containing 127 mM of oleic acid bound to albumin and 30 µCi of ^{14}C-leucine; 4 mM of ethanol were added at the beginning and an additional 3 mM were added 120 min later to experimental, but not to control, perfusates. In the presence of ethanol, secretion of total very low density lipoproteins (VLDL) into the medium increased significantly from 1099 to 1686 µg/g of liver, primarily due to increased triglyceride secretion. The specific activity of apoprotein in the VLDL fraction increased significantly from 122 to 247 cpm/µg in the presence of ethanol. Ethanol had no effect on low- or high-density lipoprotein fractions. Triglyceride concentrations in perfusion medium increased significantly from 2498 to 4203 µg/g of liver, and fatty acid concentrations increased from 2.43 to 3.52 mM/ml. The total lipid content of the liver decreased by 8.55 mg/g of liver in controls but increased significantly by 6.16 mg/g of liver in the presence of ethanol. Differences between the triglyceride and cholesterol contents of the liver were also significant, but no appreciable difference was observed for phospholipids. After 4 hr of perfusion, the fatty acid uptake of the liver was significantly lower in the presence of ethanol (34 mM/g) than in its absence (44 mM/g). Thus, these ethanol-induced changes in lipid metabolism are similar to ethanol-induced type IV hyperlipoproteinemia in man, which results mostly from increases in free fatty acids.

5415 SIMILARITY OF ARTERIAL AND INTRAVENOUS VASOPRESSIN ON PORTAL AND SYSTEMIC HEMODYNAMICS.

(E.) Barr, J. W.; Lakin, R. C.; Roesch, J. (Univ. Oregon Health Sci. Cent., Portland, Ore.). *Gastroenterology* 69(1):13-19, 1975.

The effects of superior mesenteric arterial and i.v. infusions of vasopressin and low- and high-dose i.v. infusions of vasopressin on splanchnic and systemic hemodynamics were compared in 20 anesthetized dogs. Injections of 5-10 g of microspheres into the portal circulation in five dogs of the first group (10 dogs) resulted in an immediate increase of portal pressure from a mean of 7.1 to 14.8 mm Hg. This level of increase lasted for 5-10 min after which portal pressure gradually fell and stabilized at a mean of 10.7 mm Hg. Comparison of selective arterial and i.v. infusions showed no statistically significant difference between the degree of changes in portal flow, portal and systemic blood pressure, and cardiac output. Only the superior mesenteric artery flow showed a greater decrease with the selective arterial injection. In the second group of 10 dogs, infusion of 14.0 mU/kg/min caused sharp falls in the superior mesenteric artery flow, portal vein flow and portal pressures, which reached their lowest levels in about 3-5 min. After the infusion, all parameters returned to normal levels, reaching the base line at the mean period of 55 min. Infusion of 2.75 mU/kg/min caused gradual decreases (about 10 min) and resulted in a maximal fall in superior mesenteric artery flow to 51% base line, in portal flow to 56% base line, and in portal pressures to 73% base line. The mean period of return to normal was 35 min. The applicability of these findings in dogs with normal or only slightly increased portal pressure to patients with liver disease and portal hypertension can only be established by clinical trials. The findings indicate that an easily applied i.v. infusion of vasopressin could again become the primary method for vasoconstrictive therapy of massive bleeding from varices.

5416 ACUTE LIVER INJURY BY VINYL CHLORIDE: INVOLVEMENT OF ENDOPLASMIC RETICULUM IN PHENOBARBITAL-PRETREATED RATS.

(E.) Reynolds, E. D.; Jaeger, R. J.; Murphy, S. D. (Peter Bent Brigham Hosp., Boston, Mass.). *Environ. Health Perspect.* 11:227-233, 1975.

An ultrastructural description of acute liver injury by vinyl chloride in male Holtzman rats pretreated with phenobarbital is presented. Daily consumption of phenobarbital was approximately 10 mg/100 g rat. Treated and nontreated rats were exposed to 5% vinyl chloride for 6 hr once or to 5% vinyl chloride for 6 hr each on five consecutive days. Twenty-four hr after the onset of a single exposure of 5% vinyl chloride, there was diffuse vacuolization of the cytoplasm of centrilobular liver parenchyma and focal areas of necrosis of midzonal parenchyma in phenobarbital-pretreated rats. Vacuolization involved approximately two-thirds of the hepatic parenchyma, and midzonal necrosis was focal throughout most of the liver and became extensive and confluent toward the dorsal aspect. In contrast, livers of animals exposed to vinyl chloride without phenobarbital pretreatment appeared normal. Livers of phenobarbital-pretreated animals exposed to 5% vinyl chloride on five consecutive days contained broad tracts of stroma depleted of parenchymal cells which correspond in distribution and extent to the areas of necrosis seen at 24 hr. Vacuolated liver parenchymal cells in phenobarbital-pretreated rats killed 24 hr after the onset of exposure to 5% vinyl chloride revealed extensive dilation of the cysternae of the rough endoplasmic reticulum and coalescence of the smooth into discrete aggregates of smooth surfaced tubules conspicuously flecked with areas of increased electron opacity. The ultrastructural observations that the acute liver lesion produced by vinyl chloride primarily involves components of the endoplasmic reticulum, coupled with the fact that phenobarbital enhances injury, suggest that this organelle is the primary site of generation of toxic metabolites from vinyl chloride.

5417 ALPHA FETOPROTEIN: EFFECT OF HETEROLOGOUS ANTISERUM ON HEPATOMA CELLS IN VITRO. *(E.)* Mizejewski, G. J.; Young, S. R.; Allen, R. P. (Div. Lab. Res., New York State Dep. Health, Albany). *J. Natl. Cancer Inst.* 54(6):1361-1367, 1975.

The cytotoxic effect of rabbit antisera against mouse alpha-fetoprotein (AFP) on mouse hepatoma cells was studied. Mouse BW7756 hepatoma cells and C57L/J muscle fibroblasts were grown in culture to near confluency, washed, and grown in Eagle's minimum essential medium-Hanks' balanced salt solution containing either 4% immunized (anti-AFP) or 4% nonimmunized rabbit serum. Cytotoxic antibody assays were also carried out on fresh tumor cell suspensions. The BW7756 cells synthesized AFP *in vitro*, the AFP being immunologically identical to that circulating in the sera of hepatoma-bearing mice. In the cytotoxicity assays, the presence of intact and/or inactivated anti-AFP serum inhibited the growth of the AFP-producing cells. The cytotoxic effects of the antiserum depended on both exposure time and serum concentration. The cytotoxicity was complement independent, as demonstrated by studies with heat-deactivated serum devoid of extrinsic complement. Specificity of the antisera for the target cells was demonstrated by absorption with purified mouse AFP. The results could be explained by the postulated presence of AFP on the hepatoma cell surface.

5418 INFLUENCE OF SUBTOTAL HEPATECTOMY ON PEROXISOMES AND PEROXISOMAL ENZYMES OF RAT LIVER AND ISOLATED LIVER CELL FRACTIONS. *(E.)* Goldenberg, H.; Heuttinger, M.; Boeck, P.; Kramar, R. (Dep. Med. Chem., Univ. Vienna, Austria). *Histochemistry* 44(1):44-47, 1975.

The influence of subtotal hepatectomy on peroxisomes and peroxisomal enzymes of rat liver and isolated liver cell fractions was investigated in Sprague-Dawley rats. The activities of peroxisomal enzymes were followed one to ten days after subtotal (60-70%) hepatectomy in homogenates prepared from regenerating livers and in cell fractions isolated from them. Catalase activity was depressed in the total liver homogenate as well as in the mitrochondrial and soluble fractions; it did not change appreciably in the microsomal and lysomal fractions. α-Hydroxyacid oxidase behaved in a similar fashion. In contrast to these enzymes, urate oxidase activity remained unchanged in total liver homogenate, whereas it decreased in mitrochondrial and increased in lysosomal fractions and microsomal fractions during the first five days after operation. These results agree well with the assumption that microbody proliferation is initiated by the fragmentation of large peroxisomes. Biochemical examinations were paralleled by morphological and histochemical studies. The number of peroxisomes increased during the first day after partial hepatectomy, and this was accompanied by a decrease in particle size. During the first mitotic wave (24-36 hr postoperative), the number of peroxisomes/cell was reduced by about half. After this time, the number and size of the particles began to increase. Positive staining of ribosomes was frequently observed in the vicinity of peroxisomes after the application of the cytochemical catalase reaction (alkaline diaminobenzidine medium). This phenomenon is interpreted to represent a diffusion artifact rather than the cytochemical identification of newly synthesized catalase.

5419 INFLUENCE OF PHOSPHOLIPIDS ON LIVER DAMAGE. I. CARBON TETRACHLORIDE POISONING AND ALTERATIONS IN AMINO ACID UPTAKE, PEROXIDATION, SIALIC ACID CONTENT, AND LYSOSOMAL ENZYMES. *(E.)* Gerber, G. B.; Bartsch, G. G.; Deroo, J. (Dep. Radiat. Biol., d'Centre Etude Nucleaire, Mol, Belgium). *Acta Hepatogastroenterol. (Stuttg.)* 22(3):175-180, 1975.

Changes in peroxidation, amino acid uptake [α-amino isobutyrate], sialic acid content and lysosomal enzymes were investigated in male Wistar rats and male BALB/c$^+$ mice after carbon tetrachloride poisoning and treatment with phospholipids. The animals received 1 ml of a 10% phospholipid suspension for 7 days prior to administration of CCl_4 by stomach tube. The labeled α-amino isobutyrate (1 μCi) was injected i.p. 1 hr or 18 hr before sacrifice. CCl_4 was given 6 or 24 hr before sacrifice. Homogenates were made of liver, muscle, heart and brain tissue. The uptake and retention of α-amino isobutyrate in liver increased markedly during CCl_4 poisoning. Phospholipids did not alleviate this effect and seemed to delay release of α-amino butyrate by liver. In CCl_4 poisoned rats, the uptake of α-amino butyrate was diminished in the heart but enhanced in the brain. No changes were seen in muscle. Total sialic acid in liver increased 24 hr after administration of CCl_4. Free sialic acid increased slightly in liver of CCl_4 treated rats and decreased in the brain of CCl_4 and phospholipid treated animals. Peroxides and peroxide formation were determined by the thiobarbituric acid reaction. Preformed peroxides were not affected by CCl_4 poisoning but they were diminished by phospholipid treatment. Peroxide formation was significantly greater in rats not receiving phospholipids and was markedly increased 24 hr after CCl_4 poisoning. More preformed peroxides were present in mouse than in rat liver. Peroxide formation was enhanced in mouse liver poisoned with CCl_4, but protection with phospholipids had little effect. Lysosomal enzymes were slightly influenced by phospholipid treatment and/or CCl_4 poisoning, except for a slight increase in free catheptic activity in CCl_4 poisoned mouse liver. The observed increase in catalytic peroxide formation, as well as the higher levels of peroxides in poisoned mouse liver early after intoxication, suggests that peroxides participate in the hepatotoxicity of CCl_4. Peroxidation appears to be the primary symptom of CCl_4 intoxication, with change in protein synthesis only a secondary effect.

5447 CHANGES IN THE ACTIVITIES OF ENZYMES LOCATED AT DIFFERENT SITES IN THE CELL FOLLOWING HETEROTOPIC AUXILIARY LIVER TRANSPLANTATION IN RATS. *(Ger.)* Bode, C.; Paidlick, A.; Zelder, O.; Jerusalem, C. R.; Bode, J. C. (Med. Clin., Univ. Marburg, Germany). *Verh. Dtsch. Ges. Inn. Med.* 80:427-429, 1974.

5448 α-NAPHTHYLISOTHIOCYANTE-INDUCED CHOLESTASIS IN THE RAT LIVER: EFFECT ON GLUCOCORTICOID ADMINISTRATION ON THE METABOLITES OF CARBOHYDRATE METABOLISM. *(Ger.)* Wolfert, W.; Ohnemus, H.; Goebell, H. (Cent. Intern. Med. Pediatr., Univ. Ulm, Germany). *Verh. Dtsch. Ges. Inn. Med.* 80:432-435, 1974.

5449 DETECTION OF A CELL COAT IN HEPATOCYTES IN MONOLAYER CULTURE WITH THE AID OF THE PHYTOHEMAGGLUTININ CONCANAVALLIN. *(Fr.)* Charbonne, F.; Perissel, B.; Padieu, P.; Turchini, J. P. (Fac. Med., Clermont-Ferrand, France). *C. R. Acad. Sci.* [*D*] *(Paris)* 280(13):1583-1585. 1975.

5450 THE EFFECT OF A FOOD ADDITIVE, THE ANTIOXIDANT DI-tert.-BUTYLHYDROXY-TOLUENE (BHT), ON ELECTRON TRANSPORT AND THE COUPLING OF OXIDATION AND PHOSPHORYLATION IN RAT LIVER MITOCHONDRIA. *(Fr.)* Pascal, G.; Terroine, T. (Nat. Inst. Agron. Res., Jouy-en-Josas, France). *C. R. Acad. Sci.* [*D*] *(Paris)* 280(15):1833-1836, 1975.

5451 HYDROXYLATION OF DERIVATIVES OF ANILINE AND AMINOANTIPYRINE (1-PHENYL-2,3-DIMETHYL-5-AMINOPYRAZOLONE) IN LIVER ENDOPLASMATIC RETICULUM. *(Rus.)* Archakov, I. I.; Karuzina, I. I.; Tveritinov, V. N.; Kokareva, N. S. (N. I. Pirogov 2nd State Med. Inst. Moscow, USSR). *Biokhimiia* 40(1):32-39, 1975.

5452 PROSTAGLANDIN E_1: ANOMALOUS EFFECTS ON GLUCOSE PRODUCTION IN RAT LIVER. *(E.)* Wheeler, G. E.; Epand, R. M. (Health Sci. Cent., Hamilton, Canada). *Mol. Pharmacol.* 11(3):335-339, 1975.

5453 DETERMINATION OF DICUMAROL METABOLITES IN BILE OF RATS. *(E.)* Conway, W. D.; Lee, F. H.; Neufeld, L. (Sch. Pharm., State Univ. New York, Buffalo). *J. Pharm. Sci.* 64(7):1158-1162, 1975.

5454 THE METABOLISM OF SOME FOLATES IN THE RAT. *(E.)* Beavon, J. R. G.; Blair, J. A. (Dep. Chem., Univ. Aston, Birmingham, England). *Br. J. Nutr.* 33(3):299-308, 1975.

5455 VITAMIN B_{12} NUTRITION AND METABOLISM IN THE BABOON (Papio cynocephalus). *(E.)* Siddons, R. C.; Jacob, F. (Wellcome Trust Res. Lab., Nairobi, Kenya). *Br. J. Nutr.* 33(3):415-424, 1975.

5456 THE INFLUENCE OF ISO-ENERGETIC AMOUNTS OF SUCROSE AND STARCH ON SERUM ALBUMIN CONCENTRATIONS AND LIVER COMPOSITION OF WEANLING RATS GIVEN A LOW-PROTEIN DIET. *(E.)* Grimble, R. F.; Dickerson, J. W. T. (Dep. Biochem., Univ. Surrey, England). *Nutr. Metabol.* 17(5):272-281, 1974.

5457 IDENTIFICATION OF ORNITHINE AND ARGININE CONJUGATES OF CHOLIC ACID BY MASS SPECTROMETRY. *(E.)* Myher, J. J.; Marai, L.; Kuksis, A.; Yousef, I. M.; Fisher, M. M. (Banting Best Dep. Med. Res., Toronto, Canada). *Can. J. Biochem.* 53(5):583-590, 1975.

5458 RIBOSOME ACCUMULATION IN 3-METHYLCHOLANTHRENE-INDUCED LIVER GROWTH IN ADULT MALE RATS. *(E.)* Argyris, T. S.; Heinemann, R. (Upstate Med. Cent., Syracuse, N.Y.). *Exp. Mol. Pathol.* 22(3):335-341, 1975.

5459 CONJUGATED METABOLITES OF ESTRIOL IN RAT BILE. *(E.)* Nambara, T.; Kawarada, Y. (Pharm. Inst., Tohoku Univ., Sendai, Japan). *Chem. Pharm. Bull.* 23(3):698-700, 1975.

5460 NUCLEAR PROTEIN CHANGES IN RAT HEPATOMAS CORRELATING WITH GROWTH RATE. *(E.)* Lea, M. A.; Koch, M. R.; Morris, H. P. (New Jersey Med. Sch., Newark). *Cancer Res.* 35(7):1693-1697, 1975.

5461 THERMAL AND PHOTOCHEMICAL REACTIONS OF BILIRUBIN IX-α. *(E.)* McDonagh, A. F. (Dep. Med. Pharm. Chem., Univ. Calif., San Francisco). *Ann. N.Y. Acad. Sci.* 244:553-569, 1975.

5462 ON MECHANISMS IN HYPERAMMONEMIC COMA--WITH PARTICULAR REFERENCE TO HEPATIC ENCEPHALOPATHY. *(E.)* Hindfelt, B. (Dep. Neurol., Univ. Hosp., Lund, Sweden). *Ann. N.Y. Acad. Sci.* 252:116-123, 1975.

5463 THE ENVIRONMENT OF FUNCTION OF LIVER AND RED BLOOD CELLS. *(E.)* Drabkin, D. L. (Dep. Biochem., Univ. Pa., Philadelphia). *Ann. N.Y. Acad. Sci.* 244:603-623, 1975.

5464 STUDIES ON THE SH⇌SS EQUILIBRIUM IN BIOLOGICAL MEDIA. V. ON THE DETERMINATION OF SULFHYDRYL GROUPS IN TISSUES. *(E.)* Olinescu, R.; Uleu, C. (Clin. Hosp. Fundoni, Bucharest, Romania). *Rev. Roum. Biochim.* 11(4):283-289, 1974.

5465 IN VIVO ASSESSMENT OF LIVER SIZE IN THE RAT. *(E.)* Leach, K. G.; Karran, S. J.; Wisbey, M. L.; Blumgart, L. H. (Welsh Nat. Sch. Med., Cardiff, Wales, U.K.). *J. Nucl. Med.* 16(5):380-385, 1975.

5466 T-CELL DEPENDENCE OF IMMUNE RESPONSE TO HEPATITIS B ANTIGEN IN MICE. *(E.)* Roberts, I. M.; Bernard, C. C.; Vyas, G. N.; Mackay, I. R. (Walter Eliza Hall Inst. Med. Res., Victoria, Australia). *Nature* 254(5501):606-607, 1975.

5467 AN IMPROVED NONSUTURE METHOD FOR PORTACAVAL ANASTOMOSIS IN THE RAT. *(E.)* Funovics, J. M.; Cummings, M. G.; Shuman, B. A. L.; James, J. H.; Fischer, J. E. (Mass. Gen. Hosp., Boston). *Surgery* 77(5):661-664, 1975.

5468 METABOLISM OF LEUCINE AND ALANINE IN GROWING RATS FED THE DIETS WITH VARIOUS PROTEIN TO ENERGY RATIOS. *(E.)* Tanaka, H.; Yamaguchi, M.; Kametaka, M. (Dep. Anim. Sci. Agric. Chem., Univ. Tokyo, Japan). *Agric. Biol. Chem.* 39(2):507-514, 1975.

5469 SOME ASPECTS OF THE BIOSYNTHESIS OF RIBOSOMAL STRUCTURAL PROTEINS IN REGENERATING RAT LIVER. *(E.)* Ogata, K.; Tsurugi, K.; Nabeshima, Y. (Niigata Univ. Sch. Med., Japan). *Acta Biol. Med. Ger.* 33(5-6):963-969, 1974.

5470 THE HORMONAL CONTROL OF GLUCONEOGENESIS BY REGULATION OF MITOCHONDRIAL PYRUVATE CARBOXYLATION IN ISOLATED RAT LIVER CELLS. *(E.)* Garrison, J. C.; Haynes, Jr., R. C. (Univ. Va. Sch. Med., Charlottesville). *J. Biol. Chem.* 250(8):2769-2777, 1975.

5471 INTRACELLULAR LOCALIZATION OF THE 3-HYDROXY-3-METHYLGLUTARYL COENZYME A CYCLE ENZYMES IN LIVER. SEPARATE CYTOPLASMIC AND MITOCHONDRIAL 3-HYDROXY-3-METHYLGLUTARYL COENZYME A GENERATING SYSTEMS FOR CHOLESTEROGENESIS AND KETOGENESIS. *(E.)* Clinkenbeard, K. D.; Reed, W. D.; Mooney, R. A.; Lane, M. D. (Johns Hopkins Univ. Sch. Med., Baltimore, Md.). *J. Biol. Chem.* 250(8):3108-3116, 1975.

5472 IN VIVO INCORPORATION OF CYTIDINE-MONOPHOSPHATE-CILIATINE INTO RAT LIVER LIPIDS. *(E.)* Tamari, M.; Cassaigne, A.; Lacoste, A. M.; Nevzil, E. (Biochem. Lab., Univ. Bordeaux II., France). *Biochimie* 57(1):97-103, 1975.

5473 LIVER CHANGES IN PIGS FED A DIET LOW IN PROTEIN AND HIGH IN FAT AND CHOLESTEROL. *(E.)* Gupta, P. P.; Tandon, H. D.; Ramalingaswami, V. (All-India Inst. Med. Sci., New Delhi, India). *Indian J. Med. Res.* 62(11):1659-1672, 1974.

5474 STUDIES ON METABOLISM IN RATS WITH ETHIONINE-INDUCED FATTY LIVER. *(E.)* Ramakrishna Rao, P.; Ramakrishnan, S. (Jawaharal Inst. Post-Grad. Med. Educ., Pondicherry, India). *Indian J. Biochem. Biophys.* 11(3):252-255, 1974.

5475 SUBCELLULAR DISTRIBUTION OF PYROPHOSPHATE PHOSPHOHYDROLASE IN THE RAT LIVER. *(E.)* Dumitru, I. F.; Filipescu, G.; Niculescu, S.; Iordachescu, D.; Balteanu, E. (Dep. Biochem., Inst. Biol. Sci., Bucharest, Romania). *Rev. Roum. Biochim.* 11(3):167-192, 1974.

5476 THE ACTION OF REDUCED GLUTATHIONE ON TRYPTOPHAN OXYGENASE. *(E.)* Olinescu, R.; Pascu, E. (Clin. Hosp. Fundeni, Bucharest, Romania). *Rev. Roum Biochim.* 11(3):185-192, 1974.

5477 IN VITRO METABOLISM OF POLYCHLORINATED BIPHENYLS-^{14}C. *(E.)* Greb, W.; Klein, W.; Coulston, F.; Golberg, L.; Korte, F. (Albany Med. Coll., N.Y.). *Bull. Environ. Contam. Toxicol.* 13(4):424-432, 1975.

5478 INFLUENCE OF CYTOPLASMIC FACTORS ON PROTEIN SYNTHESIS IN RAT LIVER. *(E.)* Von Der Decken, A. (Wenner-Gren Inst. Exp. Biol., Stockholm, Sweden). *Acta Biol. Med. Ger.* 33(5-6):839-843, 1975.

5479 INFLUENCE OF PHENOBARBITONE ON THE SIZE AND ACTIVITY FOR PROTEIN SYNTHESIS OF LIVER POLYRIBOSOMES FROM FASTED RATS. *(E.)* Ragnotti, G.; Aletti, M. G. (Inst. Gen. Pathol., Milan, Italy). *Acta. Biol. Med. Ger.* 33(5-6):855-858, 1974.

5480 EFFECT OF PHENOBARBITAL AND CARBON TETRACHLORIDE ON SODIUM DEHYDROCHOLATE METABOLISM IN THE GUINEA-PIG. *(E.)* Chenderovitch, J.; Raizman, A.; Infante, R. (INSERM, Hosp. Saint-Antoine, Paris, France). *Biol. Gastroenterol. (Paris)* 63(7): 265-274, 1974.

5481 SULFATED GLYCOPROTEINS IN NORMAL HUMAN BILE. *(E.)* Nagashima, H.; Suzuki, N.; Yosizawa, Z. (Tohoku Univ. Sch. Med., Sendai, Japan). *Tohoku J. Exp. Med.* 113(3):225-229, 1974.

5482 FOLIC ACID POLYGLUTAMATE CONJUGASE ACTIVITY IN LIVER OF RATS RECEIVING DIPHENYLHYDANTOIN. *(E.)* Honda, Y.; Arakawa, T. (Tohoku Univ. Sch. Med., Sendai, Japan). *Tohoku J. Exp. Med.* 113(2):197-199, 1974.

5483 INDUCTION OF CHOLANGIOCARCINOMA FOLLOWING TREATMENT OF A RHESUS MONKEY WITH AFLATOXIN. *(E.)* Tilak, T. B. G. (Dep. Patho., Nat. Inst. Nutr., Hyderabad, India). *Food Cosmet. Toxicol.* 13(2):247-249, 1975.

5484 ADRENERGIC RECEPTORS IN RAT LIVER II. EFFECTS OF PHENYLEPHRINE, ISOPROTERENOL AND ADRENERGIC BLOCKING AGENTS ON GLUCONEOGENESIS IN PERFUSED LIVER. *(E.)* Hagino, Y.; Nakashima, M. (Nagoya Univ. Sch. Med., Japan). *Jpn. J. Pharmacol.* 24(3):373-381, 1974.

5485 HISTOPATHOLOGICAL STUDIES OF THE EFFECTS OF CYTOCHROME c ON CARBON TETRACHLORIDE-INDUCED LIVER DAMAGE AND ON THE LIVERS OF AGED RATS. *(E.)* Ohnishi, H.; Hayashi, Y.; Ogawa, N.; Yajima, G.; Aihara, K. (Nippon Med. Coll., Tokyo, Japan). *Jpn. J. Pharmacol.* 24(3):425-432, 1974.

5486 THE EFFECT OF THYROIDECTOMY ON THE SUBCELLULAR Mg DISTRIBUTION IN RAT LIVER. *(E.)* Magalhaes, M. C. D. (Lab. Pharmacol., Inst. Gulbenkian Ciencia, Oeiras, Portugal). *Life Sci.* 16(7):1089-1094, 1975.

5487 INTERFERENCE OF ETHANOL IN HEPATIC CELLULAR METABOLISM. *(E.)* Lieber, C. S. (VA Hosp., Bronx, New York). *Ann. N.Y. Acad. Sci.* 252: 24-50, 1975.

5488 PROTEIN SYNTHESIS IN THE HEPATOCYTE. *(E.)* Oratz, M.; Rothschild, M. A.; Schreiber, S. (VA Hosp., New York, N.Y.). *Ann. N.Y. Acad. Sci.* 252:57-62, 1975.

5489 INTERFERENCE OF ETHANOL IN CELLULAR METABOLISM. *(E.)* Lundquist, F. (Dep. Biochem., Univ. Copenhagen, Denmark). *Ann. N.Y. Acad. Sci.* 252:11-20, 1975.

5490 ALTERATIONS IN HEPATIC CHROMATIN TEMPLATE AVAILABILITY DURING INFECTION. *(E.)* Earp, H. S. (U.S. Army Med. Res. Inst. Inf. Dis., Fort Detrick, Md.). *Am. J. Physiol.* 228(4):1183-1187, 1975.

5491 TOXICOLOGICAL IMPLICATIONS OF THE MIXED-FUNCTION OXIDASE CATALYZED METABOLISM OF CARBON DISULFIDE. *(E.)* Dalvi, R. R.; Hunter, A. L.; Neal, R. A. (Vanderbilt Univ. Sch. Med., Nashville, Tenn.). *Chem.-Biol. Interact.* 10(5):347-361, 1975.

5492 EVALUATION OF PERFUSED LIVER VIABILITY. *(E.)* Ruwart, M. J.; Kaminski, D. L.; Jellinek, M. (St. Louis Univ., Mo.). *Fed. Proc.* 34(3):395, 1975.

5493 DISTRIBUTION OF NEWLY FORMED FATTY ACIDS AMONG GLYCEROLIPIDS OF ISOLATED PERFUSED RAT LIVER. *(E.)* Kuksis, A.; Myher, J. J.; Marai, L.; Yeung, S. K. F.; Steiman, I.; Mookerjea, S. (Banting Best Dep. Med. Res., Toronto, Canada). *Can. J. Biochem.* 53(5):509-578, 1975.

5494 DISTRIBUTION OF DIPEPTIDASE ACTIVITY BETWEEN LYSOSOMES AND SOLUBLE FRACTION OF RAT LIVER. *(E.)* Taylor, S. L.; Tappel, A. L. (Dep. Food Sci. Technol., Univ. California, Davis). *Can. J. Biochem.* 53(5):502-508, 1975.

5495 NUCLEAR PROTEIN-KINASE ACTIVITY IN PERFUSED RAT LIVER STIMULATED WITH DIBUTYRYL-ADENOSINE CYCLIC 3':5'-MONOPHOSPHATE. *(E.)* Castagna, M.; Palmer, W. K.; Walsh, D. A. (Sch. Med., Univ. California, Davis). *Eur. J. Biochem.* 55(1):193-199, 1975.

5496 HEPATIC CARBOHYDRATE METABOLIC ALTERATIONS DURING ENDOTOXIC AND TRAUMATIC SHOCK. *(E.)* Filkins, J. P.; Buchanan, B. J.; Cornell, R. P. (Stritch Sch. Med., Maywood, Ill.). *Circ. Shock* 2(2):129-135, 1975.

5497 THE EFFECT OF DIETARY VITAMIN E ON GLUTATHIONE-INDUCED LIVER MITOCHONDRIAL SWELLING FROM MICE TREATED WITH 3'-4-METHYL-4-DIMETHYLAMINOAZOBENZENE. *(E.)* Block, J. A.; Roy, R. M. (Dep. Biol. Sci., Sir George Williams Univ., Montreal, Canada). *Experientia* 31(5):537-538, 1975.

5498 ORTHOTOPIC LIVER TRANSPLANTATION UTILIZING A VASCULAR STAPLING INSTRUMENT. *(E.)* Barron, P. T.; Vogelfanger, I. J.; Waddell, W. G. (Dep. Surg., Univ. Ottawa, Ontario, Canada). *Br. J. Surg.* 62(6):438-440, 1975.

5499 INDUCTION OF HEPATITIS IN ADULT SYRIAN HAMSTERS BY H-1 VIRUS. *(E.)* Henry, C. J.; Diorio, A. F. (Allegheny General Hosp., Pittsburgh, Pa.). *Proc. Soc. Exp. Biol. Med.* 149(1):23-28, 1975.

5500 EFFECT OF CARBON TETRACHLORIDE ON BILIARY EXCRETION OF CERTAIN FOREIGN ORGANIC COMPOUNDS IN THE RAT. *(E.)* Barakat, M. Z.; Abou-El-Makarem, M. M. (Dep. Biochem., Azhar Univ., Cairo, Egypt). *Bull. Acad. Pol. Sci. (Biol.)* 22(7-8):465-469, 1974.

5501 AN ELECTRON MICROSCOPIC STUDY OF THE HEPATOCYTES IN EXPERIMENTALLY INDUCED SHOCK CONDITIONS. *(E.)* Ohba, H.; Aihara, K.; Masugi, Y.; Yajima, G. (Nippon Med. Sch. Tokyo, Japan). *J. Clin. Electron Microsc. (Tokyo)* 7(3-4):363-364, 1974.

5502 ULTRASTRUCTURAL CHANGES OF THE LIVER AND KIDNEYS AND LUNGS IN EXPERIMENTALLY INDUCED THERMAL BURNS. *(E.)* Joong, S. T.; Youn, K. H.; Yajima, G.; Asano, G.; Hirayama, T.; Hayashi, M.; Kuno, Y.; Arai, K.; Tooyama, M.; Miyazaki, H. (Dep. Pathol., Kyunpook Nat. Univ., Japan). *J. Clin. Electron. Microsc. (Tokyo)* 7(3-4):365-366, 1974.

5503 ULTRASTRUCTURAL STUDIES ON EXPERIMENTAL PHOSPHOLIPIDOSIS AFTER GALACTOSAMINE INDUCED HEPATIC INJURY IN RAT LIVER CELLS. *(E.)* Takino, T.; Sugino, S.; Sugihara, T.; Okanoue, T.; Horii, Y.; Masuda, M. (Kyoto Prefectural Univ. Med., Japan). *J. Clin. Electron Microsc. (Tokyo)* 7(3-4): 372-373, 1974.

5504 LONG-TERM STRUCTURAL ALTERATIONS OF THE MOUSE LIVER THROUGH DL-α-TOCOPHEROL OVERDOSE. *(E.)* Kurono, C.; Watari, N.; Koyama, K. (Nagoya City Univ. Med. Sch., Japan). *J. Clin. Electron Microsc. (Tokyo)* 7(3-4):379, 1974.

5505 THE EFFECT OF ASPIRIN (ACETYL SALICYLATE) ON MACROMOLECULE TURNOVER IN RAT KIDNEY AND LIVER. *(E.)* Wheldrake, J. F. (Sch. Biol. Sci., Univ. South Australia, Bedord). *Experientia* 31(5): 559-560, 1975.

5506 HEPATIC RADIATION INJURY: EARLY AND LATE. *(E.)* Kinzie, J. J.; Swartz, H.; Hensley, G.; Griem, M. L. (Dep. Radiol., Univ. Chicago, Ill.). *Radiat. Res.* 62(3):543, 1975.

5507 HEPATIC LEVELS OF CYCLIC AMP IN NORMAL AND LEAD-SENSITIZED RATS AFTER TREATMENT WITH BACTERIAL ENDOTOXIN. *(E.)* Gartner, S. L. (Naval Med. Res. Inst., Bethesda, Md.). *Experientia* 31(5): 566-567, 1975.

5508 INFLUENCE OF PARTIAL HEPATECTOMY ON LATE STRUCTURAL CHANGES IN THE LIVER FOLLOWING THE LOCAL IRRADIATION. *(E.)* Jovanovic, D. A.; Bemelmans, D. H. (Inst. Canc. Kapucijnenvoer, Leuven, Belgium). *Radiat. Res.* 62(3):543, 1975.

5509 HEPATIC FUNCTION AND VASCULAR ALTERATION FOLLOWING PARTIAL LIVER X-IRRADIATION IN THE RAT. *(E.)* Jackson, K. L.; Christensen, G. M. (Dep. Radiol., Univ. Washington, Seattle). *Radiat. Res.* 62(3):543-544, 1975.

5510 THE DEVELOPMENT OF A NEW METHOD OF HEPATECTOMY BY RADIATION OF MICROWAVES. *(E.)* Osaka, A. (Sapporo City Hosp., Japan). *Bull. Soc. Int. Chir.* 33(3):166-171, 1974.

5511 STIMULATION OF LIVER REGENERATION AND COMPENSATORY KIDNEY HYPERPLASIA BY PASSIVE TRANSFER OF SPLEEN CELLS. *(E.)* Pliskin, M. E.; Prehn, R. T. (Fox Chase Cancer Cent., Philadelphia, Pa.). *J. Reticuloendoendothel. Soc.* 17(5):290-299, 1975.

LIBRARY U. OF I.

5512 RELEASE OF LYSOSOMAL ENZYME β-GLUCURONIDASE AFTER HEPATIC CRYOSURGERY. *(E.)* Nagasue, N. (Kyushu Univ. Sch. Med., Fukuoka, Japan). *Arch. Surg.* 110(6):713-716, 1975.

5513 ELECTRONOMICROSCOPIC MORPHOMETRIC CHANGES IN THE LIVER CELL OF RATS FOLLOWING ADMINISTRATION OF ALCOHOL AND ALCOHOL-RESERPIN. *(E.)* Dragiev, M.; Hristozova, A.; Mitkov, D. (I. P. Pavlov Higher Med. Inst., Plovdiv, Bulgaria). *Folia Med. (Plovdiv)* 16(2):83-93, 1974.

5514 ALLOTRANSPLANTATION IN STUDIES OF HEPATIC PHYSIOLOGY. *(E.)* Ranson, J. H. C.; Eng, K.; Rapaport, F. T.; Localio, S. A. (New York Univ. Sch. Med., N.Y.). *Transplant. Proc.* 7(1):759-762, 1975.

5515 DESCRIPTION OF THE ANHEPATIC STATE AND ACUTE HEPATIC FAILURE: EXPERIMENTAL STUDY IN PIGS. *(E.)* Galmarini, D.; Tarenzi, L.; Vercesi, G.; Beffagna, B.; Cantaluppi, G.; Mantovani, A.; Pellegrini, S.; Giradello, D.; Vitali, B. (Surg. Clin., Univ. Milan, Italy). *Surg. Ital.* 4(2):102-117, 1974.

5516 LIPIDS IN THE LIVER OF SQUIRREL, AFTER CARBON TETRACHLORIDE POISONING. *(E.)* Rana, S. V. S. (Dep. Zoology, D. A. V. Coll., Muzaffarnagar, India). *Acta Histochem.* 51(2):214-219, 1974.

5517 TECHNIQUE FOR ASSESSMENT OF LOCAL EFFECTS OF SUBSTANCES FOUND IN BILE UPON OPENING PRESSURE OF CHOLEDOCHODUODENAL JUNCTION. *(E.)* Tansey, M. F.; Innes, D. L.; Martin, J. S.; Kendall, F. M. (Temple Univ. Sch. Dent. Pharm., Philadelphia, Pa.). *J. Pharm. Sci.* 64(7):1174-1177, 1975.

5518 ULTRASTRUCTURAL EVIDENCE OF THE HEPATOTOXIC EFFECT OF HALOTHANE IN RATS FOLLOWING IN-UTERO EXPOSURE. *(E.)* Chang, L. W.; Lee, Y. K.; Dudley, Jr., A. W.; Katz, J. (Dep. Pathol. Anesthesiol., Univ. Wisconsin, Madison). *Can. Anaesth. Soc. J.* 22(3):330-338, 1975.

5519 THE RATE OF DEGRADATION OF LIVER PROTEINS. *(E.)* Kim, Y. S.; Choi, B. H.; Kim, Y. (St. Louis Univ. Sch. Med., Mo.). *Exp. Mol. Pathol.* 22(3):342-349, 1975.

5520 ON THE PROBLEM OF A COMMON HEPATIC TRANSPORT PROCESS FOR STERIODS. UPTAKE OF ^{3}H-OUBAIN, ^{3}H-TAUROCHOLIC ACID AND ^{3}H-CORTICOSTERONE INTO RAT LIVER SLICES. *(E.)* Erttmann, R. R.; Damm, K. H. (Dep. Pharmacol., Univ. Hamburg, W. Germany). *Arch. Int. Pharmacodyn.* 214(2):232-239, 1975.

5521 HISTOLOGICAL EFFECTS OF LIPIDS ON THE LIVER AND SPLEEN OF MICE. *(E.)* Stuart, A. E.; Smith, I. I. (Dep. Pathol., Univ. Edinburgh, Scotland). *J. Pathol.* 115(2):63-71, 1974.

5522 UTILIZATION OF AMINO ACIDS BY THE ISOLATED PERFUSED SHEEP LIVER. *(E.)* Lindsay, D. B.; Jarrett, I. G.; Mangan, J. L.; Linzell, J. L. (A.R.C. Inst. Anim. Physiol., Babraham, England). *Q. J. Exp. Psychol.* 60(2):141-149, 1975.

5523 EFFECT ON GUINEA-PIGS OF FEEDING NITROSOMORPHOLINE AND ITS PRECURSORS IN COMBINATION WITH ASCORBIC ACID. *(E.)* Akin, F. J.; Wasserman, A. E. (U.S. Dep. Agric., Athens, Ga.). *Food Cosmet. Toxicol.* 13(2):239-242, 1975.

5524 AFLATOXIN B$_1$ HYDROXYLATION BY HEPATIC MICROSOMAL PREPARATIONS FROM THE RHESUS MONKEY. *(E.)* Krieger, R. I.; Salhab, A. S.; Dalezios, J. I.; Hsieh, D. P. H. (Dep. Environ. Toxicol., Univ. Calif., Davis). *Food Cosmet. Toxicol.* 13(2):211-219, 1975.

5525 RIBOFLAVIN AND MOUSE HEPATIC CELL STRUCTURE AND FUNCTION. MITOCHONDRIAL OXIDATIVE METABOLISM IN SEVERE DEFICIENCY STATES. *(E.)* Hoppel, C. L.; Tandler, B. (Dep. Pharmacol., Case Western Reserve Univ., Cleveland, Ohio). *J. Nutr.* 105(5):562-570, 1975.

5526 INTERACTIONS OF CADMIUM WITH COPPER, IRON, ZINC AND MANGANESE IN OVINE TISSUES. *(E.)* Doyle, J. J.; Pfander, W. H. (Anim. Sci. Res. Cent., Univ. Mo., Columbia). *J. Nutr.* 105(5):599-606, 1975.

5527 FREE RADICAL EVOLUTION IN RAT LIVER FOLLOWING THE INGESTION OF DAB. *(E.)* Duchesne, J.; Goutier, R.; Marechal, R.; Van De Vorst, A. (Dep. Atomic Mol. Phys., Univ. Liege, Belgium). *Phys. Med. Biol.* 20(2):305-309, 1975.

5528 CARBOXYMETHYL HORSE-LIVER ALCOHOL DEHYDROGENASE. LIGAND-BINDING AND KINETIC PROPERTIES OF THE CYSTEINE-46-MODIFIED ENZYME. *(E.)* Reynolds, C. H.; McKinley-McKee, J. S. (Univ. Edinburgh Med. Sch., Scotland). *Arch. Biochem. Biophys.* 168(1):145-162, 1975.

5529 REGULATION OF RAT LIVER β-HYDROXY-β-METHYLGLUTARYL COENZYME A REDUCTASE ACTIVITY AND CHOLESTEROL LEVELS OF SERUM AND LIVER IN VARIOUS DIETARY AND HORMONAL STATES. *(E.)* Lakshmanan, M. R.; Dugan, R. E.; Nepokroeff, C. M.; Ness, G. C.; Porter, J. W. (VA Hosp., Madison, Wis.). *Arch. Biochem. Biophys.* 168(1):89-95, 1975.

5530 METABOLISM OF CHLOROBENZENE WITH HEPATIC MICROSOMES AND SOLUBILIZED CYTOCHROME P-450 SYSTEMS. *(E.)* Selander, H. G.; Jerina, D. M.; Daly, J. W. (Nat. Inst. Arthritis, Metab., Dig. Dis., Bethesda, Md.). *Arch. Biochem. Biophys.* 168(1):309-321, 1975.

5531 EFFECT OF CLOFIBRATE ON THE ADENOSINE TRIPHOSPHATASE ACTIVITY OF RAT LIVER MITOCHONDRIA. *(E.)* Panini, S. R.; Kurup, C. K. R. (Dep. Biochem., Indian Inst. Sci., Bangalore, India). *Arch. Biochem. Biophys.* 168(1):188-197, 1975.

SECRETION AND METABOLISM

Intestine

5561 ENZYME-HISTOCHEMICAL AND ELECTRON MICROSCOPE STUDIES OF THE CIRCADIAN RHYTHM IN RAT INTESTINAL MUCOSA. *(Ger.)* Schafer, V. A.; Hohn, P.; Mika, H.; Allbach, G. (Inst. Pathol., Johannes Gutenburg Univ., Mainz, Germany). *Acta Histochem. (Jena)* 48(2):301-319, 1974.

Circadian rhythms of the small intestine were studied in Sprague-Dawley rats which were screened from outside disturbances. The animals were divided into six groups of seven rats each, and sections of the bowel were removed at six fixed points at the following times of the day: 20, 24, 4, 8, 12, and 16 hr. The bowel sections were removed from locations ranging from the duodenum, jejunum and ileum to the start of the ascending colon. Enzyme functions were evaluated by electron microscopy and histochemistry (alkaline phosphatase, acid phosphatase, glucose-6-phosphatase, nucleotidase, ATP, leucinaminopeptidase, LDH, succinodehydrogenase, monoaminooxidase, and glucose-6-phosphatedehydrogenase). The hydrolases in particular showed clear-cut fluctuations of activity. In most cases the values in the afternoon and night hours were significantly higher than in the early morning and day time hours. The findings with the dehydrogenases were less uniform. G-6PDH and MAO showed relatively small differences of activity at various times of the day, whereas SDH showed a maximum at 8 hr and LDH a peak at 8 hr and 24 hr. The data presented are in agreement with the concept of the existence of circadian fluctuations of activity in the intestinal mucosa which in a general sense are an expression of the nocturnal activity of the rat.

5562 LYSOSOMAL CHANGES IN THE GUT OF RATS AFTER CHRONIC TREATMENT WITH PHENOBARBITAL. *(E.)*

Rivera-Calimlim, L.; Bosmann, H. B.; Penney, D. P.; Lasagna, L. (Univ. Rochester Sch. Med. Dent., N.Y.). *Biochem. Pharmacol.* 24(11-12):1161-1166, 1975.

The effect of long-term oral phenobarbital administration on the lysosomal enzyme activity of the intestine was studied in male Sprague-Dawley rats. Phenobarbital in distilled water solution (100 mg/kg/day) was administered by intragastric tube for 8 weeks. Matched controls were treated with distilled water. The intestinal transport of ^{14}C-methionine and ^{14}C-D-xylose in everted jejunal sacs, the ultrastructure of the jejunum, and the lysosomal enzyme activity of the jejunum were subsequently studied. Significant increases in the lysosomal enzyme activities in the intestine were observed 1 and 2 months after the beginning of phenobarbital treatment. As early as 1 month after the commencement of treatment, the activities of α-glucosidase, β-galactosidase, β-*N*-acetyl-galactosaminidase, β-*N*-acetyl-glucosaminidase, β-xylosidase, and acid phosphatase were increased, as were cathepsin-like and trypsin-like activities; the activities of α-mannosidase and α-fucosidase increased only after 2 months of treatment. Ultrastructural changes in the jejunum of the drug-treated rats were also observed; these included increased agranular endoplasmic reticulum and ribosomal particles and increases in the acid-phosphatase-positive dense bodies and coated vesicles in the absorptive cells of the intestine. There were no gross morphological changes in the intestine and there were no major alterations in the morphology of the goblet cells or in the mitochondria, terminal web, microvillus projections, Golgi apparatus, or nuclei of the absorptive cells. In addition, the mucosal transport of ^{14}C-methionine and ^{14}C-D-xylose was not altered. Thus, chronic administration of phenobarbital causes biochemical and morphological changes in the intestine; this dose level corresponds to a dose of about 600 mg in man, which is within the daily dose range administered to human patients.

5563 REGIONAL AND CELLULAR LOCALIZATION OF GLYCOSYLTRANSFERASES IN RAT SMALL INTESTINE: CHANGES IN ENZYMES WITH DIFFERENTIATION OF INTESTINAL EPITHELIAL CELLS. *(E.)*

Kim, Y. S.; Perdomo, J.; Ochoa, P.; Isaacs, R. A. (Veteran's Admin. Hosp., San Francisco, Calif.). *Biochim. Biophys. Acta* 391(1):39-50, 1975.

Optimal assay conditions were determined for four glycosyltransferases in rat small intestinal mucosal homogenates and the regional distribution and cellular localization of these enzymes was studied. Samples of jejunum and ileum were prepared from male Wistar rats, homogenized and incubated with a mixture containing Fetuin II or Fetuin I acceptor, buffer, $MnCl_2$, ATP, UDPglucose, UDP(U-^{14}C)galactose or CMP-N-acetyl(4,5,6,7,8,9-^{14}C)-neuraminic acid, Triton X-100, and enzyme. For each glycosyltransferase, similar levels of activity were found in duodenal, proximal jejunal, and distal ileal segments; the activities of the galactosyltransferases being lower in the distal jejunal-proximal ileal segments. Planar section studies indicated that undifferentiated crypt cells had significantly higher levels of sialyltransferase activities of the jejunum and ileum than the mature villous cells. A similar crypt-to-villous gradient was found for a galactosyltransferase in the ileum. Requirements for the galactosyltransferase assay included Mn^{2+}, Triton X-100, UDPglucose, and acceptor, while the sialyltransferase activity required Triton X-100 and acceptor. With Fetuin II as acceptor, the optimal conditions for the assay of the two galactosyltransferases were pH 6.0, 45 C, and 10 mM Mn^{2+}; with ovine submaxillary mucin as acceptor, the optimum assay conditions were pH 7.0, 37 C, and 40 mM $MnCl_2$. For the sialyltransferase assays, pH 6.1 and 30 C were optimal. The results suggest that the glycoprotein synthesis may be active on the undifferentiated crypt cells and that certain glycosyltransferases may serve as marker enzymes for cellular differentiation in the intestine.

5564 OCCURRENCE OF H_2-RECEPTORS FOR HISTAMINE IN THE GUINEA-PIG INTESTINE. *(E.)*

Bareicha, I.; Rocha E Silva, M. (Fac. Med., Sao Paulo, Brazil). *Biochem. Pharmacol.* 24(11-12):1215-1219, 1975.

The specific anti H_2 agent, burimamide, was used to analyze the stimulatory effects of histamine on the isolated guinea-pig ileum, and the proportion of H_2/H_1 receptors was calculated by the application of Clark's equation to data obtained in the presence and absence of burimamide. Isolated strips of guinea-pig ileum and duodenum were perfused with medium containing 10^{-7} M atropine; dose-response curves were obtained by adding (in triplicate or quadruplicate) increasing doses of histamine in the absence (control) and presence of 10^{-6} M burimamide. Burimamide potentiated the stimulatory effect of histamine on the guinea-pig ileum, an effect which was attributed to the relaxing effect induced by H_2-receptors present in the preparation. Similar results were obtained with pieces of guinea-pig duodenum. On the basis of Clark's equation, the proportion of H_2/H_1 receptors in the ileum was calculated to be 15.7%, while the average value for the duodenum was 12.4%. This small percentage of H_2/H_1 receptors may account for the fact that only the smallest concentrations of histamine appeared to be potentiated by burimamide and that this effect tended to disappear as the concentrations of histamine approached those giving maximal contraction.

5565 STUDIES ON THE BRUSH BORDER MEMBRANE OF THE MOUSE DUODENUM. I. MEMBRANE ISOLATION AND ANALYSIS OF PROTEIN COMPONENTS. *(E.)*

Billington, T.; Nayudu, P. R. V. (Dep. Zool., Monash Univ., Victoria, Australia). *J. Membr. Biol.* 21(1-2):49-64, 1975.

The proteins, carbohydrates and lipids of the brush border membrane of the mouse duodenum were analyzed using duodenal segments from adult Swiss mice. Brush border membranes were isolated from the villus epithelial cells of the segments, solubilized in Tris-sodium dodecyl sulfate buffer, and analyzed by sodium dodecyl sulfate-polyacrylamide gel electrophoresis. Preparations of these membranes were not contaminated by other organelles as judged from electron micrographs of sectioned brush-border pellets. Electrophoresis of the brush border proteins revealed a reproducible Coomassie Brilliant Blue pattern of 17 bands. By comparing the brush border protein band positions with those of standard proteins run concurrently on sodium dodecyl sulfate-polyacrylamide gel slabs, it was estimated that the 17 proteins and subunits had molecular weights ranging from over 250,000 to around 16,000 daltons. Periodate-fuchsin sulfite staining showed that the five slowly migrating, high molecular weight proteins were glycoproteins. The two proteins of smallest molecular size reacted positively with Oil Red O but had very small amounts of lipophilic amino acid residues, indicating that the lipid extractable from the gels in these areas was a contaminant and not bound to the proteins.

5566 EFFECT OF STASIS ON INTESTINAL ENZYME ACTIVITIES. *(E.)* Gracey, M.; Thomas, J.; Houghton, M. (Princess Margaret Child. Med. Res. Found., Perth, Western Australia). *Aust. N.Z. J. Med.* 5(2):141-144, 1975.

The intestinal mucosal activities of lactase, sucrase, maltase, alkaline phosphatase, and N-acetyl-β-glucosaminidase were studied in rats with surgically-induced upper intestinal stasis. Upper jejunal blind loops were made in adult Wistar rats. After 4-8 weeks tissue specimens were taken from the blind loop, the jejunum 5 cm proximal to the junction with the loop, and the jejunum 5 cm distal to the loop; specimens were also taken from the duodenojejunal junction in normal control rats. Activities of the three disaccharidases were significantly reduced in all three anatomical regions studied, but the reduction was more marked in the blind loop specimens than in those from the proximal or distal jejunum. Activities of alkaline phosphatase and N-acetyl-β-glucosaminidase were also significantly reduced in the distal gut and blind loop tissues; in addition, alkaline phosphatase was significantly reduced in the proximal gut. The results suggest a causal relation between the degree of overgrowth of the small intestinal microflora, the extent of bile salt deconjugation, and the degree of mucosal damage in the blind-loop animals; they also suggest that there was a considerable degree of damage to the lysosymes in this experimental model. The pathogenetic significance of these findings in relation to the "contaminated small-bowel syndrome" in man is unclear, but they suggest that there is an important and previously ignored mucosal lesion in this syndrome.

5567 LOCALIZATION OF SUBSTANCE P-LIKE IMMUNOREACTIVITY IN MOUSE GUT. *(E.)* Nilsson, G.; Larsson, L. I.; Hakanson, R.; Brodin, E.; Pernow, B.; Sundler, F. (Dep. Pharmacol., Karolinska Inst., Stockholm, Sweden). *Histochemistry* 43(1):97-99, 1975.

Specific antibodies against synthetic substance P were used to localize this peptide in the mouse intestine. Sectioned duodenal and proximal colonic specimens from female mice were treated with substance P antiserum and examined under the fluorescence microscope using the indirect immunofluorescence method. Strong immunofluorescence was observed in numerous nerve fibers of the myenteric plexus in the colon but not in the duodenum. The immunofluorescent nerve fibers encircled the ganglionic cells, which were nonfluorescent, and extended from the plexus in between bundles of smooth muscle. Immunofluorescence was also observed in scattered epithelial cells in the mucosa of both colon and duodenum, their numbers being much greater in the latter than the former. The immunoreactivity of these endocrine-like cells was of lower intensity than that of the nerve fibers of the myenteric plexus. In number, shape, and distribution, the immunoreactive mucosal cells resembled the enterochromaffin cells. Thus, substance P-like immunoreactivity occurs in the myenteric plexus of the proximal colon and in epithelial, possible endocrine, cells of the mucosa.

5568 LOCALIZATION OF THE MONOGLYCERIDE PATHWAY ENZYMES IN THE VILLUS TIPS OF INTESTINAL CELLS AND THEIR ABSENCE FROM THE BRUSH-BORDER. *(E.)* Negrel, R.; Ailhaud, G. (Cent. Biochim., Univ. Nice, France). *FEBS Lett.* 54(2):183-188, 1975.

The localization of monoglyceride pathway enzymes within the intestinal epithelial cells of the rat and pig was studied. Intestinal epithelial cells were fractionated, and purified brush-border vesicles were prepared. Aminopeptidase, alkaline phosphatase, cytochrome c oxidase, NADPH-cytochrome c reductase, Acyl-coenzyme A (CoA):monoglyceride and diglyceride acyltransferases, Na$^+$, K$^+$-ATPase ouabain sensitive activity, inorganic P, and N-acetylglucosaminyltransferase were assayed. Acyl-Coa:monoglyceride acyltransferase was localized in the villus tips of both the rat and pig intestinal cells. The acyl-CoA:diglyceride acyltransferase showed a similar pattern, with a ratio of mono:diglyceride acyltransferase equal to 1:3. Sucrose density gradient analysis and precipitation of the brush-border membrane vesicles by aminopeptidase antibodies indicated that the acyl-CoA:monoglyceride acyltransferase was not present in the brush-border fraction. The small amount of enzyme activity responsible for the monoglyceride esterification in the brush-border fraction is due to contamination by membranous structures. The results demonstrate that the acyl-CoA:monoglyceride acyltransferase (as well as the acyl-Coa:diglyceride acyltransferase), the specific marker of the monoglyceride pathway, can be used as a marker of differentiation for intestinal cells. The membranous structures to which the monoglyceride acyltransferase is attached may be some smooth endoplasmic reticulum in continuity with the cytoplasmic membrane.

5569 EFFECT OF ACUTE DIETARY ALTERATION UPON INTESTINAL LIPID SYNTHESIS. *(E.)* Mansbach, C. M., II. (VA Hosp., Durham, N.C.). *Lipids* 10(6):318-321, 1975.

The specific activities of 3 enzymes engaged in complex lipid synthesis, diglyceride acyltransferase, cholinephosphotransferase, and lysolecithin acyltransferase, were studied in intestinal mucosa of hamsters fed 2 meals of either saline, hydrolyzed casein, or corn oil in a 5.5-hr period. The animals were sacrificed 4 hr later and the small intestine divided into 4 equal segments; the mucosa of each segment was scraped to yield villous tip and crypt preparations, from which low-speed supernatant and microsomal fractions were derived. Enzyme assays, thin layer chromatography, and protein and radioactivity determinations were made. In the most proximal intestine, saline feeding was associated with reduced specific activities of all 3 enzymes in villous tips when compared with the 2 calorie-supplemented groups. In the most distal intestine, oil feeding increased the activity of lysolecithin acyltransferase and cholinephosphotransferase 2-fold as compared to casein-fed hamsters; diglyceride acyltransferase was increased 1.5-fold. The response of lysolecithin acyltransferase and diglyceride acyltransferase to fat feeding was incomplete when compared to hamsters fed a fat-supplemented diet for 7 days, suggesting that their pattern of response to fat was similar to sucrase response to sucrose feeding. By contrast, the response of cholinephosphotransferase to fat feeding was complete at 24 hr, suggesting that it responds in a manner similar to the glycolytic enzymes.

5570 THE "FAT RAT": A NEW EXPERIMENTAL JEJUNOILEAL BYPASS MODEL. *(E.)* Madura, J. A.; Csicsko, J. F.; Cooney, D. R.; Grosfeld, J. L. (Indiana Univ. Sch. Med., Indianapolis). *J. Pediatr. Surg.* 10(3):349-352, 1975.

Morphologic and metabolic alterations induced by jejunoileal bypass were studied in a unique obese experimental animal referred to as the "fat rat". A 90% jejunoileal bypass was performed in 20 genetically obese Zucker fat rats (500-600 g) and 20 Sprague-Dawley rats (350-400 g). Twenty unoperated growing rats of each strain served as controls. All of the animals were evaluated daily for weight loss, postoperative complications, and survival. At the end of 40 days, the animals were sacrificed and liver sections were evaluated microscopically. All rats with a jejunoileal bypass lost weight; the most rapid loss occurred during the 1st postoperative week. At 40 days, the mean weight loss for the 19 surviving operated Sprague-Dawley rats was 50 g; the controls had a mean weight gain of 35 g. The 16 surviving operated fat rats had a weight loss of 175 g while the 20 controls had a gain of 80 g. Minimal fatty infiltration of the liver was seen in 1 of 20 Sprague-Dawley controls; minimal to moderate fatty infiltration was observed in all fat rat controls. Moderate fatty infiltration was observed in the operated Sprague-Dawley rats, but operated fat rats consistently demonstrated moderate to severe fatty infiltration of the liver. The data suggest that the fat rat is a valuable laboratory model for studying morbid obesity and the aftereffects of jejunoileal bypass.

5571 EFFECTS OF PHARMACOLOGIC SYMPATHECTOMY ON GUT HYPERTROPHY IN ENTERECTOMIZED RATS. *(E.)* Touloukian, R. J.; Tilson, M. D.; Roth, R. (Yale Univ. Sch. Med., New Haven, Conn.). *J. Surg. Res.* 19(1):9-11, 1975.

The effects of 6-hydroxydopamine-induced sympathectomy on the compensatory hypertrophy seen in the jejunal and ileal remnants following enterectomy were studied in rats to further define the relation between adrenergic innervation and gut hypertrophy. 6-Hydroxydopamine (75 mg/kg) was injected i.v. into male Sprague-Dawley rats; the injection was repeated after 7 days. One week after the second injection, the sympathectomized animals and a group of normal animals underwent 50% mid-enterectomy. The jejunal and ileal remnants were examined 2 months later and the villus length measured. An 80% reduction in the catecholamine concentration of the jejunum and ileum was observed 1 week and 1-2 months after 6-hydroxydopamine treatment. This treatment had no effect on the growth rate of the animals or villus height of the jejunal or ileal remnants after enterectomy. These data do not support the hypothesis that adrenergic innervation initiates or accelerates hypertrophy in the gut remnant.

5572 EFFECT OF BILE ACIDS ON ELECTRICAL PROPERTIES OF RAT COLON: EVALUATION OF AN IN-VITRO MODEL FOR SECRETION. *(E.)* Schwiter, E. J.; Hepner, G. W.; Rose, R. C. (Pennsylvania State Univ. Coll. Med., Hershey). *Gut* 16(6):477-481, 1975.

Changes in the short-circuit current and transmural electrical potential difference (pd) of the rat colon were measured as an index of the state of secretory activity of the tissue following bile acid administration. The serosa and part of the musculature were removed from proximal colonic segments taken from male Sprague-Dawley rats. The remaining tissue was incubated in Ringer solution containing bile acid (2 mM) and/or theophylline (10 mM). The short-circuit current and pd were measured before and after the addition of bile acid and theophylline. Applied to the serosal and mucosal surfaces or to the serosal surface alone, taurochenodeoxycholic acid increased the short-circuit current and pd within 2 min; this acid was without effect when applied to the mucosal surface alone. Taurochenodeoxycholic acid also produced a significant decrease in tissue resistance. When this acid was added to the mucosal and/or serosal solution after the addition of theophylline, there was no increase in short-circuit current. Taurocholic acid also increased short-circuit current and pd when applied to serosal and mucosal surfaces or the serosal surface alone; however, the taurocholic acid-induced increase in the short-circuit current following serosal application was significantly less than that seen with taurochenodeoxycholic acid. Theophylline increased the short-circuit current and pd when applied to the serosal and/or mucosal surface. Theophylline had no significant effect on either parameter when added after the serosal application of taurochenodeoxycholic acid, although it had a stimulatory effect when added after the mucosal application of this acid; pretreatment with taurocholic acid at either surface slightly reduced the effect of theophylline. In that these results are inconsistent with results obtained *in vivo*, it is concluded that this *in vitro* model has limitations for studying the mechanism of bile acid-stimulated intestinal secretion.

5573 EFFECTS OF DIETS CONTAINING DRIED WHEY ON THE LACTASE ACTIVITY OF THE SMALL INTESTINAL MUCOSA AND THE CONTENTS OF THE SMALL INTESTINE AND CECUM OF THE PIG. *(E.)* Ekstrom, K. E.; Benevenga, N. J.; Grummer, R. H. (Coll. Agricultural Life Sciences, Univ. Wisconsin, Madison, Wis. 53706). *J. Nutr.* 105(7):851-860, 1975.

The effects of long-term feeding of various levels of dried whey on the mucosal lactase-specific activities of several genetic groups of pigs were studied. Additional experiments investigated the effect of feeding a high level of lactose on the total lactase activities of intestinal mucosa and contents, as well as the distributional pattern of these activities along the intestinal tract of two breeds of swine. Feeding 0, 10, 25 or 40% dried whey in the first study did not alter the mucosal lactase-specific activity. Assay of duodenal lactase, for example, showed 0.16 μM of galactose released/mg of protein/hr in controls, compared to values of 0.22, 0.18 and 0.18, resp., for the 10%, 25% and 40% whey diets, resp. There was no significant difference between breeding groups or breed-treatment interactions. The types of breeds used were not specified. In the second study, lactase activity in the small intestine was estimated in the total activity found in 10-cm segments of each meter of intestine. Feeding a diet containing 40% whey continuously from weaning (age 5 weeks) or from age 12 weeks did not alter the total lactase activity in pigs killed at age 21 weeks. Dietary lactose tended to increase lactase activity in cecal and small intestinal contents, but the increases were not always statistically significant. Chester White pigs had approximately 3-fold greater mucosal lactase activities (815 g of lactose able to be hydrolyzed in 24 hr) than those of Hampshire pigs (268 g). It is suggested that these two breeds may be suitable models to study the relations between lactase deficiency and lactose intolerance. Further, these results indicate that the level of mucosal lactase activity of the pig small intestine is not altered by dietary lactose.

5574 RELEASE OF CHOLECYSTOKININ BY ACID. *(E.)* Barbezat, G. O.; Grossman, M. I. (VA Wadsworth Hosp. Cent., Los Angeles, Calif.). *Proc. Soc. Exp. Biol. Med.* 148(2):463-467, 1975.

The amount of cholecystokinin (CCK) released by acid was estimated *in vivo* in mongrel dogs prepared with chronic pancreatic fistulas and Thomas cannulas in the dependent portion of the stomach. Porcine secretin (1300 ng/kg/hr) was given by continuous i.v. infusion and the pancreatic secretion was allowed to reach a steady level before the infusion of HCl (or 0.15 M NaCl to controls) and phenol red into the duodenum. In some cases, additional secretin or 10% porcine CCK was given in place of the duodenal infusion. In other experiments, the pancreas was stimulated for 2 hr by: continuous duodenal perfusion with 0.16 M HCl at 12.5, 25, 50, 100, or 200 ml/hr; continuous i.v. infusion of synthetic secretin at 62.5, 125, 250, or 500 ng/kg-hr; or continuous i.v. infusion of a fixed ratio combination of synthetic secretin and CCK. The volume, bicarbonate, and protein concentrations of the pancreatic juice were measured. Duodenal infusion of 16 nM/hr of HCl with a high background dose of i.v. secretin stimulated pancreatic protein secretion to about the same extent as did 0.5 u/kg-hr of exogenous CCK. The same acid load without the secretin background gave a response equivalent to about 0.7 u/kg-hr of CCK. Thus, expressed as fractions of their respective doses for half maximal response, acid releases almost five times more secretin than CCK.

5575 PROPERTIES OF GUANYLATE CYCLASE AND LEVELS OF CYCLIC GMP IN RAT SMALL INTESTINAL VILLOUS AND CRYPT CELLS. *(E.)* De Jonge, H. R. (Fac. Med., Erasmus Univ. Rotterdam, The Netherlands). *FEBS Lett.* 55(1):143-152, 1975.

The characteristics of brush border-localized guanylate cyclase were compared with those of microsomal enzyme preparations from isolated villous and crypt cells. A variety of hormones and hormone-like substances reported to raise cyclic AMP levels in the rat small intestine, to elevate cyclic GMP in other tissues, or to affect intestinal transport functions were tested for their ability to alter the intestinal guanylate cyclase activity *in vitro* or to regulate cyclic GMP levels in isolated villous and crypt cells and in mucosal scrapings. The kinetic properties of the brush border-bound guanylate cyclase included a positive co-operative behavior indicating multiple binding sites for $MnGTP^{2-}$ and independence from free Mn^{2+} at saturating $MnGTP^{2-}$ concentrations. The kinetic patterns of the particulate gunaylate cyclase from the upper villous cell microsomes, on the other hand, showed a marked loss of co-operativity with respect to $MnGTP^{2-}$ and activation by free Mn^{2+} at high $MnGTP^{2-}$ levels. Guanylate cyclase from the crypt microsomes displayed an intermediate type of kinetic behavior. Incubation with the brushborder guanylate in the presence of 0.1% Triton X-100 gave a 2-fold rise in activity, while 1.4 mM of $CaCl_2$ slightly inhibited the enzyme at 0.3 mM Mn^{2+}free but stimulated it by 1.2-fold at 4 mM Mn^{2+}free. Strong inhibitory effects were found with PEP, oxaloacetate, and ATP or ADP. Alloxan had a slightly inhibitory effect, amino acids in physiological concentrations had a small stimulatory effect, and D-isomers were ineffective, as were NaF, glucose, choleragen, prostaglandins E_1, F_2 and A_1, concanavalin A, and a number of catecholamines, cholinergic agents, and peptide hormones. The latter agents were also ineffective in stimulating the enzyme from the villous and crypt cell homogenates, microsomes, and mucosal scrapings. The basal levels of cyclic GMP decreased from crypt to villous cells, while the guanylate cyclase activity increased. $CaCl_2$ slightly depressed the cyclic GMP levels, while alloxan strongly elevated the cyclic GMP levels but had no effect on the cyclic AMP levels. Theophylline significantly elevated the cyclic AMP levels but did not affect the cyclic GMP levels. Ionophore A-23187, choleratoxin, prostaglandins, concanavalin A, and various cholinergic agents and hormones had no effect on the cyclic GMP levels.

5576 EFFECTS OF FASTING AND FEEDING AND PILOCARPINE ON PANETH CELLS OF THE MOUSE. *(E.)* Ahonen, A.; Penttila, A. (Dep. Anat., Univ. Helsinki, Finland). *Scand. J. Gastroenterol.* 10(4):347-352, 1975.

The effects of pilocarpine and fasting, with or without refeeding, on the Paneth cells of the mouse were studied. Fasted adult mice of both sexes were treated i.p. with nialamide (500 mg/kg), followed 1.5 hr later with pilocarpine (100 mg/kg, i.p.), and 0.5 hr after that with dopamine (100 mg/kg, i.p.); controls were treated only with nialamide and dopamine. Another group of mice was fasted for 2 days, then, in some cases, allowed to eat for 2 hr, and then treated with nialamide and dopamine as above. The animals were killed 1, 2, 3, 4, 5, or 6 hr after dopamine administration and samples of the duodenum and midjejunum were stained and examined by light and fluorescence microscopy; the dopamine-labeled secretory granules of the Paneth cells were counted. Pilocarpine stimulated the extrusion of granules from the cytoplasm of the cells and significantly decreased the number of granules, whereas fasting for 2 days without refeeding significantly increased the number of granules/cell. Refeeding following 2 days fasting had no effect on the Paneth cells of the duodenum, but resulted in a significant decrease in the number of granules in the jejunal Paneth cells compared with the number seen after fasting without refeeding. The data indicate that pilocarpine is able to stimulate the secretory mechanism of the Paneth cells, and suggest that the secretory mechanisms of these cells may be regulated in a different way in various regions of the gastrointestinal tract.

5577 RESULTS OF ORTHOTOPIC HOMOTRANSPLANTATION OF THE SMALL BOWEL IN THE SWINE. *(Fr.)* Hay, J. M.; Fagniez, P. L.; Parc, R.; Kunlin, A.; Villiers, P.; Vaiman, M.; Remy, J.; Bsowsky, A.; Chomette, G.; Clot, J. P.; Nizza, P.; Garnier, H. (Appl. Radiobiol. Lab., Commis. At. Energy, JOUY-en-JOSUS, France). *Ann. GENERAL

5590 EFFECT OF ASPIRIN, BILE SALT, AND ETHANOL ON CANINE GASTRIC MUCOSAL BLOOD FLOW. *(E.)* Cheung, L. Y.; Moody, F. G.; Reese, R. S. (Univ. Utah Coll. Med., Salt Lake City). *Surgery* 77(6): 786-792, 1975.

The effect of aspirin (20 mM), sodium taurocholate (40 mM), and ethanol (25%) on gastric mucosal blood flow was studied in an exteriorized, chambered preparation of canine fundic stomach. Gastric mucosal blood flow was measured by gamma-labeled microspheres and plasma aminopyrine clearance. All three test solutions caused a significant increase in microsphere-measured mucosal blood flow which was proportional to the severity of gross mucosal injury, being greatest with bile salt and least with ethanol. Plasma aminopyrine clearance determined only a small fraction of mucosal flow measured by microspheres following injury, particularly in sodium taurocholate and ethanol experiments, where the net hydrogen ion back diffusion was greatest. The results suggest that increased gastric mucosal blood flow may be a secondary defensive response to the damage caused by these irritants and that plasma aminopyrine clearance is unreliable in quantitating mucosal blood flow changes in the presence of mucosal injury.

5591 STRUCTURAL AND HORMONAL ALTERATIONS IN THE GASTROINTESTINAL TRACT OF PARENTERALLY FED RATS. *(E.)* Johnson, L. R.; Copeland, E. M.; Dudrick, S. J.; Lichtenberger, L. M.; Castro, G. A. (Univ. Texas Med. Sch., Houston). *Gastroenterology* 68(5, Part 1):1177-1183, 1975.

The structural and hormonal properties of the gastrointestinal tract were compared in six male Sprague-Dawley rats maintained by i.v. hyperalimentation and in six sham-operated controls. Control rats gained twice as much weight (78 *versus* 34 g) as parenterally-fed animals over a 19-day period. Kidney, spleen and testes weights did not differ between the two groups. Weights of a 2 cm portion of small intestine and of whole stomach were 73% and 25% greater, resp., in the control rats. Although antral weights were unchanged, antral gastrin was decreased by 30-fold in parenterally-fed animals. Oxyntic gland area and forestomach weights were decreased by 35%. The decrease in antral gastrin occurred early within the first 8 days after initiation of hyperalimentation. Total small intestine DNA content was decreased 2-fold and the RNA:DNA ratio was increased almost 2-fold in parenterally-fed rats, suggesting gut hypoplasia with hypertrophy of remaining cells in the experimental group. Pancreatic weight was decreased by 67% in hyperalimented rats. These results indicate that oral food ingestion is necessary to maintain structural integrity of certain tissues and accessory glands of the gastrointestinal tract and to maintain normal tissue gastrin stores.

5592 FISSION OF CRYPTS IN THE SMALL INTESTINE OF THE IRRADIATED MOUSE. *(E.)* Cairnie, A. B.; Millen, B. H. (Dep. Biol., Queens Univ., Kingston, Canada). *Cell Tissue Kinet.* 8(2):189-196, 1975.

Mouse small intestine was irradiated to determine if the number of crypts is eventually restored to normal after irradiation, and to determine the mechanism of increase in crypt number. LAF1 mice were given whole body irradiation at 21 or 66 rads/min. Tritiated thymidine (100 µCi) was injected i.p. 1 hr before sacrifice. Three mice each were killed at 3, 5, 7, 14, and 21 days after irradiation at 21 rads/min. There were also three unirradiated controls. Mice given 66 rads/min were killed: three at 2, 3, 4, and 5 days; two at 6, 7, 14 and 21 days; three at 32, and two unirradiated controls at 32 days. Small pieces of epithelium were dissected from three widely separated areas of the intestine, the villi and muscular layer removed and the crypts counted. They were then placed in scintillation vials for determination of tritium activity. The number of villi in fragments from the same three areas were counted and the tritium activity determined. Crypt and villus counts were only made for the mice exposed to the lesser dose. At 1 day after irradiation, crypts were collapsed in appearance. At 3 days there were a few obvious regenerating crypts, and by 5 days there were enough regenerating crypts to begin counting (0.27 x 10^6 crypts, as compared to 1.18 x 10^6 in the controls). The number steadily increased until it approached normal at 21 days, but the crypts were larger than normal. Very large crypts were found at 4-7 days, and budding was observed on the sides and bases of many. Forked crypts, suggestive of fission, were seen from 6 days on. These were not seen before 5 days, or in controls. It is concluded that increase in crypt number is at least partially due to fission of existing crypts, and that there is probably a compensatory feedback control regulating the number of crypts/animal.

5593 CULTURE OF ZOLLINGER-ELLISON TUMOR CELLS. *(E.)* Lichtenberger, L. M.; Lechago, J.; Dockray, G. J.; Passaro, Jr., E. (Univ. California Los Angeles Sch. Med.). *Gastroenterology* 68(5):1119-1126, 1975.

astrin-secreting Zollinger-Ellison tumor cells were rown *in vitro* to allow study of the molecular form f the hormone, the kinetics of cell growth and the ffects of stimulants and inhibitors on cell growth. umor biopsies were obtained from six patients, and ncubated in a minimal essential medium at 37 C. he medium was replaced every third day, and the sed medium stored and radioimmunoassayed for gas-rin. Cells were subcultured onto coverslips, fixed, nd stained with hematoxylin and eosin. For gastrin adioimmunoassay, pure, natural G-17 gastrin was sed as both standard and label (on iodination with ^{25}I). Used medium was incubated with trypsin and ractionated by Sephadex chromotography. To calcu-ate doubling time, a 1:100 cell dilution was seeded; fter cells became adherent, various fields contain-ng single cells were marked, left for a week, and he cells/resulting clone were counted, after 7, 21, 9, and 70 hr. For electron microscopy, cells were ixed in glutaraldehyde, and postfixed and stained ith osmium tetroxide. To measure gastrin concen-ration after stimulation, old medium was replaced ith 5.0 ml fresh fetal calf medium, and 0.25 ml amples were removed at 2.5, 10, 20 and 30 min. In ll cases, explants adhered to the glass and cell utgrowths occurred within a week. Cell population onsisted of epithelial and fibroblast-like cells in arying ratios, the latter becoming predominant after -3 months. Cells increased in number exponentially, nd doubling time was 65 hr. Cultures derived from umors at the head of the pancreas or adjacent lymph odes had the highest tissue and medium hormone levels, while the lowest levels were from large liver umors. In all cases, medium gastrin concentration ecreased with time; there were negligible amounts fter 2-7 weeks. In about 5% of the cultures, gastrin was still present after 2 months. Gel filtration chromatography of culture medium showed a major peak of radioimmunoassayable gastrin before the ^{125}I-gastrin standard, with an elution volume closely corresponding to that of G-34. There was also a minor peak of gastrin eluting at the expected location of unlabeled G-17 I. Fractionation of tumor extract showed a major peak of G-17 and a minor one of G-34, the reverse of the cultured cells. Medium gastrin concentration increased 4-10 fold for 30 min after addition of fresh medium in two lines. Over 60% of the cells from a line cultured for 2 weeks contained cytoplasmic granules 150-200 nm in diameter, in contrast to the 250-300 nm diameter granules in the original tumor. Prominent rough endoplasmic reticulum and Golgi bodies were present in both. After 6 weeks in culture, less than 10% of the cells contained a few granules, while lysosomes and autophagic vesicles were more common. It is concluded that cell doubling time was 65 hr, gastrin secretion decreased with time as epithelial cells were replaced by fibroblasts, and fresh medium stimulated secretion.

5594 FUNCTIONAL STUDIES OF PEYER'S PATCHES: EVIDENCE FOR THEIR PARTICIPATION IN INTESTINAL IMMUNE RESPONSES.

(E.) Muller-Schoop, J. W.; Good, R. A. (Sloan-Kettering Inst. Cancer Res., New York, N.Y.). *J. Immunol.* 114(6):1757-1760, 1975.

The pattern of responsiveness of Peyer's patch, splenic, mesenteric, and inguinal node lymphocytes was studied in guinea pigs following p.o. and parenteral antigenic stimulation. Live bacille Calmette Guerin (BCG) bacilli or heat-killed mycobacteria (*Mycobacterium tuberculosis*) were administered to male Hartley guinea pigs *via* stomach tube; in other animals, heat-killed mycobacteria in Freund's adjuvant were injected into the left front footpad. The guinea pigs were exsanguinated and lymphocyte suspensions prepared from the intestinal Peyer's patches, spleens, and mesenteric and inguinal lymph nodes. These cultures were stimulated *in vitro* with purified tuberculin derivative (PPD) or with Clostridia. After p.o. immunization with BCG, the Peyer's patch lymphocytes showed the best *in vitro* proliferative responses to PPD. Responsiveness to Clostridia was also significant in the Peyer's patch lymphocytes and low or absent in the other lymphoid tissues examined. In animals immunized parenterally with heat-killed mycobacteria, the splenic lymphocytes reacted best to PPD, the Peyer's patch lymphocytes giving the smallest reaction. Selective elimination of B or T cells from the PPD-reactive Peyer's patch lymphocyte populations showed that the T cell-rich fraction remained responsive to PPD, while the B cell-rich fraction became unresponsive; both fractions reacted to Clostridia. The results indicate that a functional T cell population is present in the Peyer's patch and that these organs in the guinea pig are immunocompetent lymphoid organs which seem to be primarily engaged in the production of immune responses to antigens presented from the intestinal lumen.

5595 THE DIGESTIVE TRACT IN TOTAL PARENTERAL NUTRITION.

(E.) Koga, Y.; Ikeda, K.; Inokuchi, K.; Watanabe, H.; Hashimoto, N. (Kyushu Univ. Sch. Med., Fukuoka, Japan). *Arch. Surg.* 110(6):742-745, 1975.

The effects of long-term complete parenteral nutrition on the morphology of different parts of the digestive tract were studied in 8- to 10-week-old puppies. The puppies were maintained for 4 or 8 weeks on an i.v. solution providing 140 calories/kg/day; control animals were fed a commercial diet providing the same number of calories/day. The animals were killed on the last day of the experiment and measurements were made of the length and weight of the small intestine. The thickness of the mucosa and muscular coat of the small intestine and the number of cells in mitosis and the number of argentaffin cells among the epithelial cells of the jejunal crypts were also measured. In the puppies maintained on total parenteral nutrition, the development of the gastrointestinal tract was markedly disturbed, with reductions in length, weight, and thickness of all intestinal layers; in general, these changes were more marked in the 8-week experimental group. In contrast, the microscopic structures were well preserved. There was no noticeable difference between the experimental and control animals in gastric pit:gland ratio, villus:crypt ratio, cellular component, content of periodic acid-Schiff-positive substance, or the distribution of sudanophilic fat in the mucosal membrane. However, there was a reduction in the mitotic index in the jejunal crypt in the experimental animals. Growth, development, and weight gain were basically normal in the 4-week experimental animals, but weight gain was somewhat reduced in the 8-week group. Stool output of the experimental animals was scanty, and mucus stools were evacuated once or twice/week. The results suggest that in complete parenteral nutrition, cell production in the digestive tract may be decreased due to decreased cell loss. They also suggest that the passage of diet through the small intestine is essential for the development of length in this organ.

5596 IMMUNOGLOBULIN E (IgE) AND IgE-CONTAINING CELLS IN HUMAN GASTROINTESTINAL FLUIDS AND TISSUES. *(E.)* Brown, W. R.; Borthistle, B. K.; Chen, S. T. (Dep. Med., Denver VA Hosp., Colo.). *Clin. Exp. Immunol.* 20(2):227-237, 1975.

The distribution of IgE immunocytes along the intestine and the IgE content of the intestinal fluids were studied in healthy human subjects and in patients with various digestive diseases. Samples of gastric, duodenal, jejunal, rectal, and colonic tissues were examined with immunohistological and single- and double-antibody radioimmunoassay techniques; the intestinal fluid samples were also examined by single- and double-antibody radioimmunoassay and the 4 specimens containing the largest quantities of IgE were analyzed by sucrose gradient ultracentrifugation. IgE-containing cells were identified in all tissue specimens examined, although they were less numerous than IgA, IgG, and IgM immunocytes; they comprised about 2% of the total immunofluorescent-positive cell population. The total number of immunoglobulin-forming cells of all classes, the absolute number of IgE-containing cells, and the percentage of IgE-containing cells decreased along the intestine from stomach to rectum. IgE immunocytes were at least 10-fold more numerous at the bases of gastric and duodenal peptic ulcers than elsewhere in these tissues, and the number of IgE-type cells in the rectal tissues of 2 patients with Crohn's disease and 1 patient with chronic ulcerative colitis was 3- to 5-fold greater than in the rectal tissues of subjects with other or no colonic diseases. Measurable IgE was found in 92% of the intestinal fluid samples; the concentration did not differ significantly among normal subjects and patients with various digestive diseases. Sucrose gradient ultracentrifugation analysis revealed that the immunologically reactive IgE was largely present in fractions corresponding to molecules of lower molecular weight than that of albumin, which suggest that IgE in the gut contents is degraded by proteolytic enzymes. The results suggest that IgE antibodies are available for participation in local reaginic-type reactions in the gut.

5597 ESCAPE FROM VASOCONSTRICTION IN THE GASTRIC MICROCIRCULATION. *(E.)* Guth, P. H.; Smith, E. (VA Wadsworth Hosp. Cent., Los Angeles, Calif.). *Am. J. Physiol.* 228(6):1893-1895, 1975.

The possible occurrence of escape from vasoconstriction in the gastric microcirculation, and the involvement of submucosal shunt opening in this phenomenon, was studied in male Wistar rats. Using an image-splitting TV microscope recording system, the response of the gastric submucosal arterioles (13-33 µm) to 3 min of left splanchnic nerve stimulation (8 V), norepinephrine superfusion (0.2-0.7 µg/min), and vasopressin superfusion (.0025-.005 U/min) was studied. All stimuli produced initial vasoconstriction, the average maximum vasoconstriction diameter being 72-79.9% of control values. With sympathetic nerve stimulation and norepinephrine superfusion, the initial vasoconstriction was followed by escape in all animals, the average escape index (relative degree of escape from vasoconstrictor stimulation) being 0.64 after sympathetic nerve stimulation and 0.77 after norepinephrine superfusion. In neither case was significant poststimulation dilatation observed. In contrast, escape occurred in only 1 animal after vasopressin superfusion, the mean escape index in this group being -0.50; again, significant poststimulation dilatation was not observed. No arteriovenous shunts were seen. The results indicate that the gastric submucosal arterioles exhibit an escape phenomenon following adrenergic stimulation, suggesting that "autoregulatory escape" in other splanchnic beds may also be due to the relaxation of constricted vessels and not to the opening of shunts.

5598 VITAMIN B_{12} ABSORPTION IN X-IRRADIATED RATS. *(E.)* D'Souza, D. W.; Vakil, U. K.; Sreenivasan, A. (Biochem. Food Technol. Div., Bhabha At. Res. Cent., Bombay, India). *Environ. Physiol. Biochem.* 5(1):37-48, 1975.

The effect of whole-body exposure to a sublethal dose of x-irradiation on the intestinal submucosal absorption of vitamin B_{12} was studied in male Wistar rats. Weanling rats were provided with adequate nutrition or maintained on vitamin A-deficient diets; after 3 weeks, the animals were placed on low (8%) or adequate (20%) diets. Two weeks later, the animals were x-irradiated (400 rad) or were sham-irradiated. Vitamin B_{12} absorption was measured in intestinal loop segments following the injection of vitamin B_{12} (with or without gastric juice from normal rats) into several ligated intestinal segments. The distribution of radioactivity in the serum and tissues was also measured after i.p. (0.5 µCi) or p.o. (1 µCi) administration of ^{57}Co-B_{12}. The rate of absorption of vitamin B_{12} from the intestinal loops of adequately nourished rats was decreased by x-irradiation, the inclusion of gastric juice from normal rats having no effect on the rate. A severe interference in the absorption and retention of p.o. ^{57}Co-B_{12} was also observed in the irradiated rats: this was evidenced by low serum B_{12} levels, decreased organ uptake of B_{12}, and increased B_{12} excretion. However, when the vitamin was administered i.p., its uptake by various organs was not affected by x-irradiation. Atrophy of the intestinal cells in the animals maintained on a low-protein diet accentuated the adverse effects of radiation on B_{12} absorption; vitamin A deficiency had no appreciable effect on B_{12} absorption by the x-irradiated animals. A sharp drop in viable intestinal flora was observed within 24 hr after irradiation, but their numbers were found to increase after 3 days. The results suggest that the observed morphological degeneration of mucosal cells in the x-irradiated animals was the primary reason for the B_{12} malabsorption seen after x-ray exposure.

5599 INTESTINAL BLOOD FLOW: AN EVALUATION BY CLEARANCE OF XENON Xe 133 FROM THE CANINE JEJUNUM. *(E.)* Wilson, S. E.; Hiatt, J.; Winston, M.; Passaro, E., Jr. (VA Wadsworth Hosp., Los Angeles, Calif.). *Arch. Surg.* 110(7):797-801, 1975.

Blood flow to the small bowel was assessed by measuring the clearance of xenon from the canine jejunum. ^{133}Xe was injected into the submucosa and muscularis of the jejunum in five anesthetized male mongrels. A thyroid-uptake type scintillation probe was used to register isotope clearance, the rate of disappearance or "washout curve" being used to determine the tissue blood flow following varying degrees of partial aortic occlusion. The shapes of the plotted washout curves from submucosa and muscularis were characteristic and reproducible, a steep or rapid initial component being consistently followed by a slower component. The calculated xenon clearance rates for both tissues (expressed as half-times for isotope disappearance and plotted as a function of decreasing superior mesenteric artery flow) were characteristically rapid for a broad range of superior mesenteric artery flows (90-600 ml/min). With reduction of the superior mesenteric artery flow beyond 80 ml/min, the tissue clearance of xenon was markedly prolonged. Adequate perfusion of the vascular compartments of the small bowel as measured by xenon clearance was maintained until reduction of the superior mesenteric artery flow beyond 80 ml/min. The data suggest that mesenteric vascular obstruction may be considerable before tissue perfusion is markedly reduced, provided that colonic vascular auto-regulation is similar to that of the jejunum. The clearance of a xenon injection from the intestinal parenchyma may, therefore, represent a useful and readily available tool for use in the diagnosis of vascular insufficiency of the bowel.

5600 IMMUNOGENICITY OF LIPID-CONJUGATED PROTEIN IN THE INTESTINE. *(E.)* Heatley, R. V.; Stark, J. M. (Welsh Natl. Sch. Med., Cardiff). *Immunology* 29(1):143-149, 1975.

Lipid-conjugated human serum albumin (HSA) was tested for its ability to induce antibody production, molecular aggregation, and a tendency to attach to cells in female Wistar rats; the amounts of undigested antigen draining in the intestinal lymph were also measured, as was the anticomplementary activity of the antigens. HSA was acylated with lauroyl chloride; different degrees of fatty acid attachment were achieved by differing the molar ratios of lauroyl chloride to protein. Rats were immunized with untreated or lauroylated HSA by i.m. injection (1 mg followed 28 days later by 100 μg) or by injection into the lumen of the small bowel (10 mg followed 28 days later by 1 mg). *In vitro,* rat peritoneal cell suspensions were incubated for 1 hr with acylated protein or HSA exposed to the solvent mixtures required for acylation but without lauroyl chloride (CHSA). The antibody response to lauroylated HSA was significantly greater than that to untreated HSA or CHSA, the response tending to decrease with increasing degrees of acylation. Similar results were obtained with i.m. injection and injection into the small bowel, although the differences in response obtained with the acylated and nonacylated proteins were less clearly defined in the latter case. The increased immunogenicity of the acylated protein was associated with increased molecular aggregation and cellular adherence, the degree of polymerization and percentage attachment increasing with increased acylation. Acylation also reduced the drainage of undigested antigen through the lymphatics. All acylated proteins showed some anticomplementary activity, which increased with the degree of acylation. The data suggest that if lipid-associated protein with an insufficiently hydrophilic surface is absorbed from the gut, an immunogenic event may ensue which in humans might play a role in the pathogenesis of a variety of inflammatory disorders of the gastrointestinal tract for which an immunological basis has been postulated.

DIAGNOSTIC PROCEDURES

5615 ELECTROCOAGULATION BIOPSY WITH SPECIAL REFERENCE TO HISTOLOGIC DIAGNOSIS OF GASTRIC LIPOMA. *(E.)* Yoshida, T.; Nakamura, Y.; Nakamura, K.; Watanabe, H.; Tanaka, K. (Med. Coll. Miyazaki, Japan). *Gastrointest. Endosc.* 21(4):156-158, 1975.

The applicability of electrocoagulation biopsy to submucosal tumors of the stomach was illustrated in the histological diagnosis of two gastric lipomas. The two cases were initially diagnosed as submucosal tumor by roentgenologic and endoscopic examinations, with a negative result by routine biopsy, but were later proved to be lipoma by means of electrocoagulation biopsy. Submucosal tissue from intramural tumors could be obtained by biopsy through the ulcerative lesion several days after electrocoagulation. Electrocoagulation biopsy is recommended for making a histologic documentation of tumors covered by intact mucosa or of small tumors found incidentally; it is considered simple, safe, and easy.

5616 DEVELOPMENT OF AN INTRAVENOUS BILE ACID TOLERANCE TEST: PLASMA DISAPPEARANCE OF CHOLYLGLYCINE IN HEALTH. *(E.)* Korman, M. G.; LaRusso, N. F.; Hoffman, N. E.; Hofmann, A. F. (Mayo Clin., Rochester, Minn.). *N. Engl. J. Med.* 292(23): 1205-1209, 1975

The plasma disappearance of i.v. injected cholylglycine was studied in man by a radioimmunoassay to develop an i.v. bile acid tolerance test. Cholylglycine (1-7.5 mg/kg) was injected into six healthy men at 3 hr intervals at three different dosages to determine the optimal dose; 5 μM/kg was selected for subsequent tests. Forty-five healthy subjects were then injected with the optimal dose of cholylglycine and serial samples of venous blood were collected for radioimmunoassay, specific for conjugates of cholic acid. Cholylglycine disappearance was rapid (2.6 min half-life); the rate of disappearance was independent of dose between 2 and 15 μM/kg. The conjugates of cholic acid increased 10-fold, but the concentration of those bile acids returned to 1 μM by 10 min. No side effects were observed. The results suggest that cholylglycine may be an ideal substance for an i.v. tolerance test for defining hepatic functional mass and that its plasma disappearance may provide the basis for a convenient, safe and sensitive test for detection of liver disease.

5617 CASCADE STOMACH: ROENTGEN APPEARANCE AND SIGNIFICANCE. *(E.)* Keller, R. J.; Khilnani, M. T.; Wolf, B. S. (Mt. Sinai Hosp., New York, N.Y.). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 123(4):746-754, 1975.

Cascade stomach was precisely described so that it can be recognized in the erect position at the onset of a barium series. In the erect position, the presence of a posterior "ridge" which delineates a boundary between the fundus and body of the stomach was used to define the presence of a cascade configuration. Such configuration of the stomach, which is seen in the absence of significant pathologic abnormality, is most often associated with a gas distended distal transverse colon or proximal limb of the splenic flexure. True physiological or normal cascade is not very common; patients with a cascade stomach have demonstrated a variety of lesions, both intrinsic and extrinsic, primarily related to the posterior wall of the stomach. It is suggested that a cascade stomach should not be considered physiologic or within normal limits until a detailed examination of the area is performed.

5618 ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN PATIENTS WITH GASTRECTOMY AND GASTROJEJUNOSTOMY (BILLROTH II). A CASE FOR THE FORWARD LOOK. *(E.)* Katon, R. M.; Bilbao, M. K.; Parent, J. A.; Smith, F. W. (Univ. Oregon Med. Sch., Portland). *Gastrointest. Endosc.* 21(4):164-165, 1975.

The use of a fiberscopic endoscope with a forward-viewing optical system was described for cannulation through the afferent loop of a Billroth II anastomosis. Twelve procedures were performed on 10 patients with a distal gastrectomy and Billroth II gastrojejunostomy. A side-viewing fiberduodenscope was used in four patients. Delays and difficulties in identifying and entering the afferent loop and in introducing the instrument through the loop to the papilla of Vater were encountered with all four patients. With the forward-viewing fiberscope used in six patients, the afferent loop was easily identified, entered, and followed to its blind termination. The authors recommend use of the forward-viewing instrument for endoscopic cannulation of the duodenal papilla in patients with gastrojejunostomy but urge particular caution in endoscopy of the afferent limb.

5619 ENDOSCOPIC DIAGNOSIS OF GASTRIC CANCER WITH DYE SCATTERING. *(E.)* Ida, K.; Hashimoto, Y.; Takeda, S.; Murakami, K.; Kawai, K. (Murakami Mem. Hosp., Kyoto, Japan). *Am. J. Gastroenterol.* 63(4):316-320, 1975.

A dye scattering technique was used for the diagnosis of early cancer of the stomach. The examination was performed on 41 patients with early and advanced gastric cancer; indigocarmine was used in 33 cases, methylene blue in two patients, and both dyes in four cases. With routine endoscopy, 35/41 cancerous lesions were diagnosed correctly; with the dye technique, 40/41 lesions were correctly diagnosed. The morphology of the gastric mucosal surface was well defined by the dye scattering technique. In 12 lesions, the whole contour of the cancerous lesion was detected by both methods; in 20/29 lesions, the borders could be completely outlined with dye scattering but only partially defined by routine endoscopy. The dye technique allowed for delineation of minimal depressions in the gastric mucosa; depressions were seen in 12/15 patients in whom no lesion was recognized by routine endoscopy. A correlation was observed between degree of abnormality of surface structure and the depth of cancer infiltration. The indirect dye scattering method is considered helpful in the clinical diagnosis of gastric cancer by intensifying and delineating mucosal surface alterations.

5620 VALIDITY AND SENSITIVITY OF AN INTRAVENOUS BILE ACID TOLERANCE TEST IN PATIENTS WITH LIVER DISEASE. *(E.)* LaRusso, N. F.; Hoffman, N. E.; Hofmann, A. F.; Korman, M. G. (Mayo Clin., Rochester, Minn.). *N. Engl. J. Med.* 292(23):1209-1214, 1975.

A bile acid tolerance test, which measures the plasma disappearance rate of injected cholylglycine by radioimmunoassay, was studied in 36 patients with biopsy-proved chronic liver disease and compared to other conventional liver function tests. The patients were divided into two groups: one group of 25 patients had abnormal results on conventional liver function tests and were used to validate the sensitivity and reliability of the test; the other group of 11 patients had liver test results within normal limits and were used to compare the sensitivity of the cholylglycine tolerance test with that of other tests and of the fasting-state conjugated cholic acid test. Cholylglycine (5 μM/kg, i.v.) was injected into each patient and serial samples of blood were collected for determinations of conjugated cholic acid values by radioimmunoassay. In the first group of 25, fasting-state levels of conjugated cholic acid were increased in 20, but plasma disappearance of cholylglycine was delayed in all. In the other group, fasting-state levels of conjugated cholic acid were increased in 3/10, but cholylglycine disappearance was delayed in 9/11. The results suggest that the bile acid tolerance test indicates liver disease more sensitively than the fasting-state level of conjugated cholic acid, which, in turn, is more sensitive than other conventional liver tests.

5621 ^{131}I ROSE BENGAL LIVER SCANNING IN THE DIFFERENTIAL DIAGNOSIS OF NEONATAL JAUNDICE. *(E.)* Wicksman, R. S.; Adcock, D. F.; Bream, C. A.; Scatliff, J. H. (Univ. North Carolina Sch. Med., Chapel Hill). *South. Med. J.* 68(5):599-602, 1975.

The radioiodinated rose bengal abdominal scan was used as the only radioactive testing procedure in diagnosis of congenital biliary atresia in infants, and a count ratio was obtained from the scan data as an additional physiologic measurement. The 21 infants were premedicated with stable iodine, then given 10-30 μCi ^{131}I rose bengal i.v. in rough proportion to body weight. Sequential, anterior abdominal scans were usually obtained at 15 min, 1, 3, 6, 24, and 48 hr after injection. Some lateral scans were also done. Count ratio was determined by marking the point of maximal activity, then recording the 24-hr count over this point and dividing it by the maximal count rate. This indicated degree of retention of the radioisotope in the liver, and varied directly with severity of obstruction. Of 22 scans done on 21 infants, diagnosis based on scan only was incorrect in four instances (82% accuracy). In three of these, severity of the obstruction was overestimated. Eight infants were found to have biliary atresia, and 13 intrinsic liver disease, by open or needle biopsy, autopsy, or clinical course. Those with total obstruction had a mean count ratio of 0.76, while those with intrinsic liver disease had one of 0.45. It is concluded that the rose bengal scan alone had an accuracy of 82%, and that determination of count ratio, at no additional expense, would have improved the accuracy.

5622 FIBERCOLONSCOPY FOR THE DIAGNOSIS OF GRANULOMATOUS COLITIS. *(E.)* Watanabe, H.; Narasaka, T.; Imai, H.; Uezu, J. M.; Numazawa, M.; Shoji, K.; Ishikawa, M.; Yamagata, S. (Tohoku Univ. Sch. Med., Sendai, Japan). *Tohoku J. Exp. Med.* 115(3):285-296, 1975.

The pathological, radiological, endoscopic, and clinical differences between granulomatous colitis and ulcerative colitis were studied to test the effectiveness of fibercolonoscopy in diagnosis of granulomatous colitis. Observations were made on 12 cases of granulomatous colitis and 23 cases of ulcerative colitis. Granulomatous colitis showed cobblestone-like or gyrous lesions, segmentally distributed along the bowel, excepting the rectum. The lesions lacked hemorrhage or suppuration, showed microscopic evidence of transmural inflammation and non-caseating granuloma formation, and showed fissuring and stricture. Characteristic were negative tuberculin tests, diarrhea with no bleeding, palpable abdominal mass, and small bowel involvement In contrast, ulcerative colitis showed continuous, symmetrically distributed lesions, which included the rectum. Lesions were rough or granular, or showed pseudopolyposis, hemorrhage, and suppuration. There was no evidence of non-caseating granuloma formation, fissuring, fistula, or stricture. Blood in the stool and lack of small bowel involvement were characteristic. Fibercolonoscopy combined with biopsy is the only procedure that allows direct observation of the lesions. It is concluded that fibercolonoscopy is quite valuable in diagnosis of granulomatous colitis.

5623 THE "RECTO-SIGMOID INDEX". A MEASUREMENT FOR THE EARLY DIAGNOSIS OF HIRSCHSPRUNG'S DISEASE. *(E.)* Pochaczevsky, R.; Leonidas, J. C. (Mt. Sinai Hosp. Serv., City Univ. New York, N.Y.). *Am. J. Roentgenol. Radium Ther. Nucl. Ther.* 123(4): 770-777, 1975.

Barium contrast studies done on 21 newborns with biopsy-proven Hirschsprung's disease, 10 with the meconium plug syndrome, 12 normal term newborns and five with other gastrointestinal diseases were reviewed. The ratio of the widest diameter of the rectum at a level below the third sacral vertebra to that of the sigmoid loop ("recto-sigmoid index") ranged from 0.7 to 0.9 (mean=0.8) in 10 Hirschsprung's disease patients who had no definite colonic transition segment. In contrast, the indices of normal subjects ranged from 1.0 to 1.9 (mean=1.4) and those of newborns with other disease of the gastrointestinal tract ranged from 1.3 to 1.5 (mean=1.4).

Based on these results, it is suggested that the "recto-sigmoid index" may aid in the diagnosis of Hirschsprung's disease in the newborn without a definite transition segment on the barium contrast study.

5624 DETERMINATION OF SERUM LIPOPROTEIN-X FOR THE EARLY DIFFERENTIATION BETWEEN NEONATAL HEPATITIS AND BILIARY ATRESIA. *(E.)* Campbell, D. P.; Poley, J. R.; Alaupovic, P. (Univ. Oklahoma Health Sci. Cent., Oklahoma City). *J. Surg. Res.* 18(4):385-390, 1975.

A combination of lipoprotein-X determination and cholestyramine treatment was used to differentiate between neonatal hepatitis and biliary atresia. Infants (28) with cholestatic jaundice of etiology not determinable by standard testing had serum lipoprotein-X measured after a 6-hr fast. Those with a positive reaction were given 1 g cholestyramine/day p.o. for 2 weeks, followed by a second lipoprotein-X determination. Of the 28 infants, 14 proved to have biliary atresia on surgical exploration. All 14 were positive for lipoprotein-X. Of these, 13 showed a rise in serum lipoprotein-X levels after the cholestyramine treatment. The serum from the 14th was in transit for 4 days, sufficient time for the lipoprotein-X to dissociate. The remaining 14 infants had intrinsic cholestasis, 12 from neonatal hepatitis. Of the 14, five were positive for lipoprotein-X. After cholestyramine treatment, the lipoprotein-X levels dropped significantly. Six of the nine negative for lipoprotein-X were given the cholestyramine treatment; all remained negative. Of the 28 infants, 27 were diagnosed accurately (96.4%). It is concluded that lipoprotein-X determination coupled with cholestyramine treatment is an accurate and simple method of distinguishing biliary atresia and intrinsic cholestasis.

5625 EMERGENCY PERITONEOSCOPY. *(Ger.)* Baerlocher, C.; Engelhart, G.; Fahrlander, H. (Dep. Med., Univ. Basel, Switzerland). *Leber Magen Darm* 3(1):11-14, 1973.

Emergency peritoneoscopy was introduced in the authors' clinic in 1964 and to date 180 such examinations were performed corresponding with 10% of the total number of laparoscopies. Endoscopic results, shown in tabular form, covered 100 patients with blunt abdominal trauma, including 47 patients with free blood in the abdominal cavity and one with urine due to rupture of the bladder; further, 80 patients without abdominal trauma involving peritonitis, mesenterial infarct, pancreatitis and miscellaneous causes. Data are given on confirmation of the endoscopic findings with clinical course, surgery or autopsy. While the method, described as far back as 1937 and 1942, has not found general acceptance, the authors consider emergency peritoneoscopy a safe procedure, quick to carry out (normally in 10-15 min), tolerated even by seriously ill patients, and of high diagnostic value. In some aspects it may be preferable to other diagnostic procedures such as exploratory puncture or peritoneal lavage. An experienced endoscopy team, however, is a prerequisite.

5626 THE ROLE OF GLUCAGON IN ENDOSCOPIC CHOLANGIOPANCREATOGRAPHY. *(E.)* Silvis, S. E.; Vennes, J. A. (Minneapolis VA Hosp., Minn.). *Gastrointest. Endosc.* 21(4):162-163, 1975.

The effectiveness of glucagon in control of duodenal motility, in promoting efficiency in performing endoscopic cholangiopancreatography, and in preventing pancreatitis was determined in a double-blind study of 55 patients. All patients received dicyclomine (60 mg, i.m.) and atropine (0.4 mg, i.m.) before the procedure. When the duodenoscope was in position, 28 patients received 1 ml glucagon and 27 patients received 1 ml saline. Change in motility was evaluated and urine amylase was obtained. A marked subjective change in motility was noted in 8/17 patients who had received glucagon compared with 2/16 in the placebo group. Twenty-four hours after the procedure, 8% of the patients who had received glucagon and 64% of the placebo patients had an elevated urine amylase value; the mean urinary amylase value was 186 U/hr in glucagon patients and 682 U/hr in placebo patients (statistically significant). One patient who had received glucagon developed cholangitis, and one placebo patient developed mild pancreatitis. The results suggest that glucagon is a safe and valuable means of controlling duodenal motility in endoscopic pancreatocholangiography.

5627 NEW DIAGNOSTIC AND THERAPEUTIC TECHNIQUES IN THE MANAGEMENT OF PYOGENIC LIVER ABSCESSES. *(E.)* Ranson, J. H. C.; Madayag, M. A.; Localio, S. A.; Spencer, F. C. (New York Univ. Med. Cent., New York, N.Y.). *Ann. Surg.* 181(5):508-518, 1975.

The treatment of 14 patients (12 men and 2 women, aged 22-80 yr) operated on for pyogenic liver abscesses was studied. Eight cases (57%) were cryptogenic. Other abscesses were associated with biliary disease (3), abdominal sepsis (2), and trauma (1). Abscesses were present on hospitalization in 12 patients. Clinical findings included fever (101-108 F), 100%; leucocytosis, 71%; anorexia and vomiting, 50%; localized tenderness and hepatomegaly, 50%; hypoalbuminemia, 86%; hypocholesterolemia, 78%; elevated SGOT, 71%; and elevated alkaline phosphatase, 43%. Technetium hepatic scintiscans showed focal defects in 10 of 12 patients (83%), but did not detect multiple abscesses in 2 of these. Hepatic arteriography performed in 10 patients was highly accurate, outlining single abscesses in 6 and multiple abscesses in 4. Furthermore, in one patient a false positive scintiscan was demonstrated by negative arteriography, confirmed by autopsy. In 4 patients, arteriography indicated an abscess in the posterior-superior area of the right hepatic lobe. With precise anatomical localization, a transthoracic approach permitted uncomplicated drainage in each case. This approach provided excellent exposure and direct drainage for abscesses in this area. An additional therapeutic adjunct in 2 patients, with 4 and 11 abscesses each, was postoperative intraportal infusion of antibiotics through the umbilical vein. Thirteen patients (83%) recovered, one dying from pulmonary embolism. Primary hepatic abscesses occur with increasing frequency. The methods described allow more precise preoperative diagnosis and direct surgical drainage.

5628 SUPRAGASTRIC PANCREOSCOPY: LAPAROSCOPY AND BIOPSY OF THE BODY OF THE PANCREAS.

(Ger.) Meyer-Burg, J.; (Steglitz Clin., Free Univ., Berlin, Germany). *Fortschr. Med.* 91(26):1017-1019, 1975.

A report on the direct laparoscopic inspection of the pancreas and its possible value as a diagnostic tool in pancreatic diseases was presented. The operative procedure in performing a laparoscopy was briefly described and visual characteristics of the pancreas were noted in the normal state, in acute and in chronic pancreatitis, and with neoplasms of the pancreas, which are often associated with liver metastases, Courvoisier's law or cholestasis. Clinical data, cited from other publications, included 125 laparoscopies which allowed inspection of parts of the pancreas in 81 (65%) cases. These included 15 patients with pancreatic neoplasms, six patients with chronic pancreatitis, one patient after passage of acute pancreatitis, and one patient with a pancreatic pseudocyst falsely diagnosed as a tumor. In 31 cases material was removed for cytological examination, usually by multiple puncture of each organ in different locations. Admittedly, the limitations of the method reside in the fact that only protions of the pancreas (largely the surface) are accessible to inspection. Also, it does not usually serve in early recognition of a pancreatic neoplasm since most patients do not seek medical help in the beginning stage of the disease. Its chief value, therefore, is its application within the general framework of diagnosing pancreatic diseases.

5629 RADIOSELENUM PANCREOZYMIN-SECRETIN TEST AS A CLINICAL TEST FOR PANCREATIC EXOCRINE FUNCTION.

(E.) Shichiri, M.; Etani, N.; Yoshida, M.; Harano, Y.; Hoshi, M.; Shigeta, Y.; Abe, H. (Osaka Univ. Med. Sch., Japan). *Am. J. Dig. Dis.* 20(5):460-468, 1975.

The appearance of radioselenium in the protein fraction of duodenal aspirates following stimulation with pancreozymin and secretin was investigated. Pancreatic exocrine function was determined in 36 subjects: 17 were classified as normal and 19 had pancreatic diseases including chronic pancreatitis (14), pancreatic carcinoma (3), and pancreatic cyst (2). A good distinction between normal subjects and patients with pancreatic disease was obtained by measuring ^{75}Se-radioactivity in the protein fraction of duodenal aspirates; either cumulative radioactivity during the combined 80 min post-pancreozymin-secretin period or maximum ^{75}Se-specific activity during the postsecretin period was used as an index. It is suggested that this test may be useful and sufficiently reliable for detecting abnormal pancreatic exocrine function. This test can be performed simultaneously with the conventional pancreozymin-secretin test, provocative serum enzyme response to pancreozymin and secretin stimulation, and pancreatic scintiscanning. Inclusion of the cytology test may help to distinguish carcinoma from other pancreatic diseases. The combined test may provide more accurate information on pancreatic exocrine function.

5630 CRITICAL EVALUATION OF HEPATIC SCINTIANGIOGRAPHY FOR NEOPLASTIC TUMORS OF THE LIVER.

(E.) Stadalnik, R. C.; DeNardo, S. J.; DeNardo, G. L.; Raventos, A. (Univ. California Sch. Med., Davis, Sacramento Med. Cent.). *J. Nucl. Med.* 16(7):595-601, 1975.

Dynamic hepatic scintiangiography was compared with histologic and radiopaque diagnostic techniques in the evaluation of suspected hepatic neoplasms in humans. In 92 patients previously diagnosed as having hepatic metastases or normal livers, histologic examination of the liver was performed within 2 months of hepatic scintigraphy and scintiangiography; in 10 of these patients, radiopaque arteriography was also performed. Of the 92 patients studied, 23 had histologically normal livers, 10 had hepatomas, and 59 were classified as having hepatic metastases. In all 10 patients with hepatoma, the scintiangiographic and histologic observations agreed; 9 of these patients had a "tumor stain." Scintiangiograms in 51 of the patients with metastases also showed a tumor stain, and in 2 of the metastasis patients, scintiangiography revealed tumor vascularity where the scintigraphic results were normal. In 2 of 4 patients with metastases and 2 of 6 patients with hepatomas, scintiangiograms revealed tumor stain which was not evident on radiopaque arteriography. In 20 of the patients with normal hepatic tissue, both the hepatic scintigram and corresponding scintiangiogram were normal, while in 2 others both were abnormal; in 1 other patient, the scintigram was normal, but the scintiangiogram demonstrated focal arterialization due to a renal carcinoma. The results indicate that: a normal scintigram with a corresponding normal scintiangiogram make neoplastic involvement of the liver improbable; a normal scintigram and a tumor stain on the scintiangiogram of a patient with a known primary neoplasm outside the liver is suggestive of hepatic metastases; and neoplastic arterialization or tumor stain is more readily detected by scintiangiography than by radiopaque arteriography. Dynamic hepatic scintiangiography is a simple technique which should be included in the evaluation of the liver for neoplastic involvement.

5631 ABRASIVE CYTOLOGY OF THE PANCREATIC AND BILIARY DUCT IN MAN.

(E.) Weidenhiller, S.; Fluegel, H.; Rosch, W. (Dep. Med., Univ. Erlangen-Nuremberg, Germany). *Endoscopy* 7(2):72-74, 1975.

Abrasive cytological examination of the pancreatic and biliary duct was evaluated as a technique for the preoperative diagnosis of malignant tumors of the pancreas and biliary tree. A specially designed Fogarthy-catheter was run through a conventional endoscopic retrograde cholangiopancreatography tube and introduced into Vater's papilla in 25 patients; after positioning, the abrasion balloon at the tip of the catheter was inflated and withdrawn. Using this probe, abraded cell material was obtained from the pancreatic duct in 19 patients and from the common bile duct in 6 patients. Sufficient cytological material was obtained in almost all patients without noticeable complications. In 1 patient in whom a previous retrograde pancreatogram was suspicious of pancreatic carcinoma, the diagnosis was cytologically confirmed prior to surgery. The abrasion balloon technique described will probably be of value in the cytological examination of the common bile and pancreatic ducts, and will be particularly useful in cases of suspicious strictures or complete obstruction of the ductal system by malignancy.

5632 DIAGNOSTIC VALUE OF SERUM BILE ACID ESTIMATIONS IN LIVER DISEASE.

(E.) Barnes, S.; Gallo, G. A.; Trash, D. B.; Morris, J. S. (R. Free Hosp., London, England). *J. Clin. Pathol.* 28(6):506-509, 1975.

Fasting and postprandial serum bile acid concentrations were measured in normal (10 men and 8 women, aged 23-35 yr) subjects and in patients (18 men and 12 women, aged 25-65 yr) with a variety of hepatobiliary diseases. The 30 patients were histologically diagnosed as follows: cryptogenic cirrhosis (9), alcoholic cirrhosis (3), primary biliary cirrhosis (6), active chronic hepatitis (4), cholestatic syndromes (drug jaundice) (3), viral hepatitis (2), and large bile duct obstruction (3). In addition, 7 persons (5 men and 2 women, aged 18-75 yr) with hepatovenous outflow block (3) and unconjugated hyperbilirubinemia (4) were studied. In normal subjects the serum bile acid concentration ranged between 0 and 15 μM/liter. No differences were noted between the sexes or between fasting and postprandial concentrations. In 27 of the 30 patients with hepatobiliary disease, fasting concentrations were above the normal range (22-600 μM/liter). In 3 subjects with liver disease the fasting serum bile acid concentrations were normal, but 2 hr after the fatty breakfast they became markedly elevated. In 2 of these 3 subjects, other biochemical estimations (serum bilirubin, aspartate transaminase, alkaline phosphatase) were normal. Compared with the other biochemical estimations the postprandial serum bile acid concentrations were the only estimations which were consistently abnormal. In the 4 patients with unconjugated hyperbilirubinemia, both fasting and 2 hr postprandial bile acid concentrations were normal as were the liver function tests, which was expected as they had no histological liver disease. Two of the 3 with hepatic venous outflow block had normal fasting concentrations, but all had elevated postprandial serum bile acid concentrations, indicating a degree of hepatocellular dysfunction. This study shows that the 2-hr postprandial serum bile acid concentrations are elevated in patients with histological hepatobiliary disease, even when fasting concentrations and other liver function tests are normal. Despite the obvious value of serum bile acids in indicating the presence of histological liver damage, the results indicate that such measurements are of no value in distinguishing between particular liver diseases, particularly in deciding whether cholestasis is of intra- or extrahepatic origin.

5633 THE USE OF A SHORT-LIVED RADIONUCLIDE IN THE INVESTIGATION OF ACUTE BLEEDING IN THE UPPER GASTROINTESTINAL TRACT.

(E.) Pettersson, C.; Forssman, O.; Hollender, A.; Mulder, J. L. (Cent. Hosp., Boras and Ferring AB, Malmo, Sweden). *Scand. J. Gastroenterol.* 10:213-215, 1975.

The possibility of detecting and monitoring bleeding in the upper gastrointestinal tract using a short-lived radionuclide ^{113}In^{m} was investigated. *In vitro* studies were performed to confirm the protein binding of indium ions. *In vivo* studies in 2 healthy subjects showed that when the radionuclide was ingested in 0.04 M HCl, no absorption took place. The radionuclide was passed along the gastrointestinal tract and no significant binding to the stomach or the duodenum could be detected. The procedure was then studied in 28 patients with acute bleeding in the upper gastrointestinal tract. In 16 patients no signs of blood could be detected from aspirates from the duodenum or stomach. In another 4 cases, only traces of blood could be found. In the remaining 8 cases, the aspirate showed a +++ Weber reaction. In 11 cases with a positive, and in 1 case with a negative, test for blood in the aspirate, ^{113}In^{m} was injected i.v. In no patient was a higher radioactive count found in the aspirates than in controls. In all patients, tests for blood in the feces remained positive for 2 weeks or less. Current bleeding was noted in only 1 patient as judged by the injection of ^{113}In^{m}. By using this radionuclide to estimate the amount of current bleeding in the gastrointestinal tract, bleeding in the amount of 8-10 ml/hr can be detected, providing a complete collection of the contents of the gastrointestinal lumen can be performed. As the radionuclide is short-lived it can be used repeatedly in the same patient. The most striking finding of this study was that in patients with acute bleeding in the upper gastrointestinal tract but without signs of shock, the bleeding mostly ceases within a very short time after onset. Therefore, the blood in aspirates from the duodenum or stomach is obviously mostly of somewhat older origin. If bleeding is monitored by this present method, it might be possible for a patient to leave the hospital long before a negative blood test in the feces is obtained.

5634 TECHNETIUM-99m-PYRIDOXYLIDENEGLUTAMATE: A NEW HEPATOBILIARY RADIOPHARMACEUTICAL. II. CLINICAL ASPECTS.

(E.) Ronai, P. M.; Baker, R. J.; Bellen, J. C.; Collins, P. J.; Anderson, P. J.; Lander, H. (Inst. Med. Vet. Sci., R. Adelaide Hosp., South Australia). *J. Nucl. Med.* 16(8):728-737, 1975.

The new radiopharmaceutical, Technetium-99m-pyridoxylideneglutamate (^{99m}Tc-PG), was clinically evaluated in ten control subjects, 24 patients referred for the investigation of right upper quadrant abdominal pain, and 36 patients referred for investigation of jaundice. No patient preparation or premedication was used prior to the i.v. administration of 5 to 6 mCi of the compound. Sequential scintigrams were recorded for all patients, and contrast radiologic studies of the biliary tree were performed as indicated. There were no subjective symptoms or biochemical changes associated with the administration of the radiopharmaceutical. In the control subjects, the biliary tree and gallbladder were seen within 10 to 15 min of injection and within 20 min marked accumulation of radioactivity was noted in the gallbladder and gastrointestinal tract; the ^{99m}Tc-PG-cholescintigrams were normal in seven controls and the gallbladder was not visualized in the remaining three. Gallbaldder disease was present in 13 of the patients referred for investigation of right upper quadrant pain. All seven patients with acute cholecystitis and one out of four patients with chronic cholecystitis had nonvisualization of the gallbladder, whereas five patients with chronic cholecystitis and/or cholesterolosis had normal cholescintigrams; in the first group, nonvisualization of the gallbladder was also reported on the contrast studies. Cholescintigraphy was greatly inferior to contrast radiologic studies in the detection of gallbladder stones. Diagnosis of complete extrahepatic biliary obstruction was correctly made by the cholescintigram in all 11 cases in which it occurred, whereas correct diagnosis based on the cholescintigram was made in only seven out of 14 patients with incomplete extrahepatic biliary obstruction. A diagnosis of obstruction due to malignancy was correctly made in eight out of ten patients by means of a scintigraphic equivalent to Courvoisier's sign. A nonspecific pattern, consistent with incomplete biliary obstruction or hepatocellular disease, was observed on the cholescintigram in all 11 patients with hepatocellular disease. It is suggested that the ^{99m}Tc-PG-cholescintigram be used in conjunction with contrast radiologic studies in the preoperative investigation of patients with possible surgical disease of the biliary tract; the former is more appropriate in the patient with jaundice while the latter is more appropriate in the nonjaundiced patient.

5635 AN EXPERIMENTAL STUDY OF ^{99m}Tc PERTECHNETATE ABDOMINAL SCANS IN JEJUNAL INTUSSUSCEPTION: PRELIMINARY RESULTS. *(E.)* James, A. E., Jr.; Strecker, E. P.; Miller, F. J., Jr.; Bush, M. (Johns Hopkins Univ. Sch. Med., Baltimore, Md.). *J. Surg. Res.* 19(1):71-76, 1975.

The abnormalities noted on ^{99m}Tc pertechnetate abdominal scans of dogs with small bowel intussusceptions were studied. Surgical, nonreducible small bowel intussusceptions were produced in eight mongrels. At various intervals thereafter, ^{99m}Tc pertechnetate (75 µCi/kg) was administered i.v. and abdominal scans were obtained 30 min, 4 hr, and 24 hr later using a rectilinear scanner. Scans were also obtained on normal controls receiving ^{99m}Tc pertechnetate for other diagnostic studies. The animals were sacrificed 12, 24, or 48 hr after injection, the small bowel was removed, and radiographs were made. Samples of the intraluminal fluid and tissue samples were counted in a well counter and histological preparations were made. A characteristic abnormal image was seldom obtained on the abdominal scans, and even in animals giving positive results, the bowel proximal to the intussusception, not the intussusception itself, was visualized. In addition, the major concentration of radioactivity was in the intraluminal fluid proximal to the surgically-induced intussusception. Selective concentration of the radiopharmaceutical was also observed just proximal to a variety of surgically-created mechanical obstructions of the jejunum and ileum. The scans on normal dogs showed accumulation of radioactivity in the stomach and urinary bladder as well as occasional visualization in the region of the duodenum. Despite catheterization, the urinary bladder was often visualized. The results suggest that the abdominal scan abnormalities in patients with intussusception are not caused by visualization of the lesion but are due to attendant bowel obstruction.

5636 TOMOECHOGRAPHIC DIAGNOSIS OF HEPATIC POLYCYSTOSES. *(Fr.)* Weill, F.; Aucant, D.; Becker, J. C.; Eisenscher, A.; Kraehenbuhl, J. R. (Univ. Hosp. Cent., Besancon, France). *(Ann. Radiol. (Paris)* 17(7):685-689, 1974.

Tomoechography is considered an excellent tool in the diagnosis of hepatic polycystosis due to the specific character of the ultrasonic image of lesions containing echo-free zones. Six cases of hepatic polycystosis (all women) were detected in over 4000 ultrasonic examinations. In four of the patients with discrete hepatomegaly and no palpable cystic formation, hepatic polycystosis was detected by additional ultrasonic examination following the diagnosis of renal polycystosis. In the two other patients, who exhibited marked hepatomegaly, renal polycystosis was discovered secondarily. The association of renal polycystosis is evidently an important positive clue in the diagnosis of hepatic polycystosis.

5637 EXPERIMENTAL AND CLINICAL STUDIES WITH ^{131}I-BSP. *(Ger.)* Mostbeck, A.; Peschl, L.; Rettenbacher-Taubner, H.; Neumayr, A. (Wilhelmine Hosp., Vienna, Austria). *Z. Gastroenterol.* 12(7):547-556, 1974.

In vitro and *in vivo* studies demonstrated that by using ^{131}I-BSP with a high specific activity, it is possible to reduce the dose of BSP from 5 mg/kg to less than 1 mg and thus to reduce the likelihood of untoward reactions to the dye. *In vitro* studies revealed that ^{131}I-BSP had the same R_f value as inactive BSP on thin-layer chromatography, was chemically stable, and was bound almost quantitatively to serum proteins when they were precipitated with trichloroacetic or sulfosalicylic acids. In *in vivo* studies, there was a good correlation between clearance constants for the first 10 to 12 min and the 45:3-min retention values obtained with both forms of BSP. However, ^{131}I-BSP was excreted somewhat more slowly by the liver. The clearance constant was reduced by about 50% when ^{131}I-BSP and inactive BSP were administered simultaneously. When instilled into the duodenum, only 0.4 to 0.6% of ^{131}I-BSP was later detected in the blood. Although very small quantities of ^{131}I-BSP were found in the thyroid (maximum of 3-5% of the i.v. administered dose after 24 hr), iodine should be administered to block the thyroid. Good correlations were found between clearance constants and 45:3-min retention values obtained from blood samples and those obtained by measurement of radioactivity over the skull. However, the use of radiation measurements gave consistently smaller clearance constants and significantly higher retention values than were obtained with inactive BSP. These differences are attributed to the distribution of radioactive BSP between vascular and extravascular space. A comparison of clearance constants determined with ^{131}I-BSP on 198 patients (91 with no evidence of liver disease, the rest with fatty liver, acute and chronic hepatitis, compensated and decompensated cirrhosis, obstructive jaundice and intrahepatic cholestasis) gave good separation between normal subjects and those with liver diseases other than fatty liver. Of 30 histologically confirmed cases of fatty liver, only six had pathological values. All patients tolerated i.v. injections of ^{131}I-BSP, and no reactions occurred when the test was repeated after an interval of several days to several weeks.

5638 FUNCTIONAL EXAMINATION OF DEFECATION IN CHILDREN. *(Ger.)* Berger, D.; Landry, M. (Lausanne Univ. Clin., Switzerland). *Fortschr. Geb. Roentgenstr. Nuklearmed.* 121(4):428-434, 1974.

Kinematographic studies of the anorectal canal were performed during defecation on 11 children, aged 6 weeks to 10 yr, using video tape recording and image intensification. In some cases, electromyograms (EMG) were obtained from the puborectal loop and the external anal sphincter to differentiate between myogenic and neurogenic disorders. In constipated children, both under basal conditions and during defecation, anorectal angles were smaller than normal; the anal canal contracted only slightly and was generally conical in shape. The sphincter zone sometimes appeared spastic. In several constipated children, basal activity on the EMG was increased, but no pathognomonic significance was attributed to this finding. In Hirschsprung's disease involving the rectum, changes found in constipated children were more pronounced and were accompanied by dyskinesia in the aganglionic part of the large intestine. In a 10-yr-old boy who developed neurogenic constipation and spastic paresis on the right as the result of a lumbosacral fracture, both the external urethral sphincter and the anorectal region showed spastic changes because both sphincters were innervated by the sacral nerve. Classical anatomical features were totally absent in a 8-yr-old girl with meningomyelocele: the anorectal angle could not be measured, the anal canal was wide open and defecation had to be aided by abdominal pressure. An EMG of the external anal sphincter was almost a straight line. In children with high anorectal malformations, no matter what the clinical findings, the anorectal angle was smaller than in normal children and there was a certain rigidity and inactivity of the anal canal. These radiological measurements gave a rather accurate picture of the quality of continence.

5639 THE PANCREATOGRAPHIC EFFECT DURING PHARMACOANGIOGRAPHY OF THE PANCREAS. *(E.)* Schmarsow, R.; Peters, P. E. (Deutsche Klink Diagnostik, Wiesbaden, Germany). *Acta Radiol.* [*Diagn.*] *(Stockh.)* 16(1):73-80, 1975.

The value of pancreatography in distinguishing between chronic pancreatitis and carcinoma of the pancreas was investigated. Secretin (1.5 IU/kg), priscoline (0.7 mg/kg), serotonin (0.7 γ/kg), and caerulein (0.3 γ/kg) were used to enhance the pancreatographic effect. Seventy examinations were performed in 55 adult patients with possible pancreatic disorders. In a series of 174 celiac angiographies performed without drugs, the pancreatographic effect was present in 18.4%. In the 55 angiographies performed with drugs, the effect was produced in 74.5%. By injecting the contrast medium into the hepatic and splenic arteries and in a few cases into the gastroduodenal and dorsal pancreatic arteries without drugs increased the frequency of the pancreatographic effect to 43.3% (out of 30 cases). The use of drugs increased it further to 71.4% (out of 28 cases). With the addition of vasodilatory drugs, higher rates of pancreatographic effect were achieved. In 31 cases the type of pancreatographic effect was compared to pancreatic function. A homogeneous pancreatographic effect was achieved in 14 patients with normal pancreatic function. In six cases with a pathologic test, the pancreas appeared mottled. No correlation between scanning with the isotope ^{75}Se-methionin and the pancreatographic effect was found. The few cases of malignancy in this study material suggest that the pancreatographic effect is completely or partially absent in carcinoma patients. A homogeneous pancreatographic effect seems to exclude a carcinoma and a mottled effect indicates chronic pancreatitis. The absence of pancreatographic effect in carcinoma may be due to the fact that the neoplasm is mostly hypovascular and that the neoplastic tissue has an almost homogeneous dense fibrous stroma, which impedes the accumulation of the contrast medium in this region.

GASTROINTESTINAL DISEASES

ESOPHAGUS

5703 THE EPIDEMIOLOGY OF ESOPHAGEAL CANCER IN NORTH CHINA AND PRELIMINARY RESULTS IN THE INVESTIGATION OF ITS ETIOLOGICAL FACTORS. *(E.)*

Anonymous. *Sci. Sinica* 18(1):131-148, 1975.

An epidemiological survey (involving 50 million people) of the incidence of esophageal cancer in North China was carried out from 1969 to 1971. Preliminary clinical and experimental studies were also carried out on etiological factors and associated conditions, and pathogenesis and histopathology of esophageal cancer. An area with a high mortality rate from esophageal cancer was located in the southern Taihang Mountains on the borders of the Honan, Shansi and Hopei provinces. The mortality rates decreased gradually, extending out from this area in irregular, concentric belts. The highest age-sex adjusted mortality rate reached 139.80/100,000 and the lowest was 1.43/100,000, with an average mortality rate of 37.39/100,000. The male:female patient ratio averaged 1.6:1. The higher the mortality rate of a locality, the lower the difference in the sex ratio. Over 60% of the total rate was in the age group ranging from 50 to 69 yr. In counties with a high incidence of esophageal cancer, there were also greater numbers of people with epithelial dysplasia of the esophagus. The average age-sex adjusted incidence rate in Lingsien county (1959-1970) was 108.56/100,000, and the mortality rate was 99.76/100,000. Mortality rate trends showed little change over 30 yr. The ratio of esophageal cancer to cancer of the gastric cardia was 3:1; most cases were located in the middle and lower third of the esophagus. A comparative study showed that in areas of high esophageal cancer incidence, gullet cancer among chickens was also common. It is concluded that there must be a close relation between this disease and the geographical environment.

5704 BENIGN EPITHELIAL HYPERPLASIA OF THE ESOPHAGUS: GLYCOGENIC ACANTHOSIS. *(E.)*

Clemencon, G.; Gloor, F. (Canton Hosp., Olten, Switzerland). *Endoscopy* 6(4):214-217, 1974.

The epidemiology, morphology, and localization of glycogenic acanthosis of the esophagus in humans is discussed. Among 364 esophagogastroscopies performed between July 1973 and March 1974, glycogenic acanthosis of the esophagus was diagnosed in 24 patients (19 men and 5 women, average age, 64 yr). Fifteen of these patients had endoscopic signs of an incompetent cardia and 11 of these had clear endoscopic signs of reflux esophagitis. Biopsy specimens from 12 patients showed focal areas of thickened squamous epithelium with an increased number of rounded glycogen-rich squamous cells. There was no cellular atypia or dyskeratosis and no signs of inflammation. The lesions in glycogenic acanthosis consist of small, mostly multiple whitish plaques of raised hyperplastic epithelium; they are usually found on folds and can be stained dark brown or violet with Lugol's solution. Glycogenic acanthosis is often mistaken for leukoplakia on macroscopic examination, especially when the plaques are relatively large. The small plaques are missed on esophagoscopy when the lumen is not optimally distended by air insufflation or when using a very bright light. It is concluded that glycogenic acanthosis is a very frequent but harmless condition; although nothing is known of its etiology, it seems to be more frequent in cardiac incompetence.

5705 BARRETT'S ESOPHAGUS AND ADENOCARCINOMA.

(Fr.) Savary, M.; Naef, A. P.; Ozzello, L.; Roethlisberger, B. (Otorhinolaryngol. Clin., Univ. Lausanne, Switzerland). *Schweiz. Med. Wochenschr.* 105(18):575-579, 1975.

Endoscopy was used to demonstrate various forms of cylindrical epithelial heterotopia with respect to frequency, pathological associations and relationship with adenocarcinoma. Of 6168 esophagoscopies performed between 1963 and 1974 (more than half for gastroesophaegeal reflux syndrome), 164 revealed the presence of single or multiple cylindrical epithelial zones. These zones were of two distinct types: 1) cylindrical epithelial islets of the upper (19%) or lower (4%) esophagus; 2) widespread and diffuse cylindrical eipthelial heterotopia of the lower esophagus (77%). The first type was a malformation of congenital origin without pathological significance. The second type, however, would seem to enter into the category of chronic peptic esophagitis and may represent a form of epithelial cicatrization of chronic peptic ulcers. It is concluded that adenocarcinoma (15%) of the lower esophagus is associated with the second type of cylindrical epithelial heterotopia. Treatment of peptic esophagitis is advisable before it reaches the chronic stage and, in particular, before the appearance of cylindrical epithelial zones.

STOMACH

5734 EFFECT OF UNILATERAL THORACIC VAGOTOMY ON HISTAMINE-STIMULATED ACID SECRETION IN MAN. *(E.)* Basso, N.; Coloni, G. F.; Ricci, C.; Passaro, Jr., E.; Speranza, V. (VA Wadsworth Hosp. Cent., Los Angeles, Calif.). *J. Surg. Res.* 18(6):555-558, 1975.

The acid response to histamine stimulation in patients undergoing a thoracotomy for lung carcinoma was studied to determine the effect of unilateral vagotomy in man. Male thoracotomy patients (56, aged 37-62 yr) were studied pre- and postoperatively. There were five groups of patients: 1) vagus resection not necessary (32 patients); 2) vagotomy in the right diaphragm (five); 3) vagotomy at the right pulmonary hilum (five); 4) vagotomy at the left diaphragm (eight); and 5) vagotomy at the left pulmonary hilum (six). In all cases the acid response to a maximal dose of histamine (0.024 mg/kg) was measured before and after thoracotomy. The effect of unilateral vagotomy on gastric acid secretion depended on whether the right or left nerve was cut, and at what level the cut occurred. Resection of the left vagus at the level of the diaphragm reduced basal secretion and diminished acid response to histamine stimulation by 22%. No significant reduction in acid secretion was observed when vagal resection was done at the pulmonary hilum. Resection of the right vagus reduced basal secretion and the acid response to histamine stimulation by 45-50% when performed at either the pulmonary hilum or the diaphragm. These results may correlate with the observation that in man the right vagus is generally greater in size than the left. It is suggested that the right vagus is responsible for the major portion of the vagal innervation of the parietal cell mass and/or overlaps the innervation to the mucosa supplied by the left nerve. It is further concluded that unilateral right vagotomy in man may have therapeutic implications.

5735 METASTATIC INVOLVEMENT OF THE STOMACH SECONDARY TO BREAST CARCINOMA. *(E.)* Joffe, N. (Beth Israel Hosp., Boston, Mass.). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 123(3):512-521, 1975.

Roentgenologic findings associated with gastric metastases secondary to breast carcinoma (based on nine such cases) are presented, including case reports of five of these women (51 to 81 yr). Autopsy in the first case revealed disseminated breast carcinoma with gross infiltration of the wall of the stomach (predominantly the muscularis) and submucosa by tumor cells identical to those seen in the primary breast lesions. Histological examination in the third case showed tumor infiltration of the serosa, muscularis and submucosa, with marked infiltration in the subserosal region of the stomach. An upper gastrointestinal examination in the fourth case revealed at least two large ulcer craters in the region of the narrowed prepyloric segment; however, no autopsy was obtained. Biopsy of the gastric mass in the fifth case revealed anaplastic carcinoma similar in appearance to the primary breast tumor. Based on the gross pathologic findings, two main types of roentgenologic abnormalities might be expected to occur: circumscribed nodular lesions or more diffuse, infiltrative lesions. The commonest type of roentgen abnormality was that produced by diffuse intramural infiltration of the stomach resulting in a linitis plastica appearance, with narrowing of the lumen secondary to gross thickening of the gastric wall, rigidity and diminished or absent peristalsis in the involved area. Roentgenologic studies of the second type of lesion may show single or multiple discrete intraluminal filling defects with or without associated ulceration. Because of the apparent rarity of this lesion, and until more information is available concerning the incidence of the discrete nodular form of gastric metastases from breast carcinoma, it is concluded that final diagnosis must depend upon histologic confirmation even in patients with disseminated disease.

5736 HISTOLOGIC TYPES AND POSSIBLE INITIAL STAGES IN EARLY GASTRIC CARCINOMA. *(E.)* Grundmann, E. (Inst. Pathol., Univ. Munster, Germany). *Beitr. Pathol.* 154(3):256-280, 1975.

In order to determine 1) which histologic types are found in early gastric cancer, 2) whether possible precursor and initial characteristic stages exist, and 3) from which proliferative zones these arise, 2003 gastric specimens from 301 patients were examined, and a diagnosis of carcinoma was made in 45 cases. Examination of resection preparations revealed 36 cases of deep invasive stomach carcinoma and nine of early gastric cancer confined to mucosa and/or submucosa. Carcinomatous proliferations limited to mucosa or submucosa were classified in three histologic types: intestinal (adeno); mucocellular (signet ring cell); and anaplastic (solid). Mixed types were found combining the first and second, or the second and third types; one case presented a mixture of all three. Possible precursor or initial stages of all three types were found in a further 31 biopsies. Some were glandular lesions in superficial parts of the mucosa, previously described as possible preneoplastic stages of the intestinal type of early gastric cancer. "Signet ring cell drippings" from lower parts of tubule necks were recorded as an initial form of the signet ring cell type; this process is interpreted as detaching of isolated signet ring cells from a gland neck zone in progressing atypical transformation. An early neoplastic stage of the anaplastic type was identified in the gland neck dysplasia located exclusively in the antrum between surface mucosa and antrum glands, appearing rich in cells, and stretched. Early gastric cancer of this third type will arise in the same location. Conclusions from formal histogenesis suggest that the signet ring cell type and the anaplastic (solid) type might start in the lower part of the tubule necks. In consequence, the neck region of gastric glands could be the critical field of malignant transformation in gastric mucosa. It is concluded that long-term follow-up studies are needed to verify these observations and their interpretations.

5737 SURGICAL MANAGEMENT OF MENETRIER'S DISEASE WITH PROTEIN-LOSING GASTROPATHY. *(E.)*

Scott, Jr., H. W.; Shull, H. J.; Law, IV, D. H.; Burko, H.; Page, D. L. (Vanderbilt Univ. Med. Cent., Nashville, Tenn.). *Ann. Surg.* 181(5):765-777, 1975.

Case histories for three patients with Menetrier's disease and protein-losing gastropathy who were studied during a 12-yr period are presented. Characteristic findings which differentiate these patients from individuals with hypertrophic hypersecretory gastropathy, including the Zollinger-Ellison syndrome, were: 1) hypertrophy of gastric mucosa with giant rugal folds involving the fundus, cardia and body of the stomach but not the antrum; 2) mucosal hypertrophy consisting of gastric mucus-secreting cells while parietal and chief cells were diminished in number and were absent from many microscopic sections; 3) gastric secretion of large volume containing excess mucus, low to absent hydrochloric acid and protein concentrations five or six times the normal (1.7 mg/ml); 4) hypoalbuminemia and hypoglobulinemia due to loss of serum proteins from gastric mucosa into the gastric lumen; 5) rare association with gastric ulcer. Unlike patients with the Zollinger-Ellison syndrome, none of these had duodenal ulcer or multiple endocrine adenomatosis. Menetrier's disease with protein-losing gastropathy is a potentially lethal disorder of unknown cause and no specific treatment, although resection of the site of protein losses can be effective. One of the three patients presented here died before gastrectomy could be performed. The other two have remained well for 11 months and 12 yr, resp., after total gastrectomy with Roux-en-Y esophagojejunostomy and Hunt-Lawrence jejunal pouch. Because the manifestations of the disease have disappeared in these patients, and good rehabilitative results have been obtained, these procedures are recommended for patients with Menetrier's disease.

5738 THE EFFECT OF METOCLOPRAMIDE ON HUMAN GASTRIC EMPTYING AND SECRETION. *(E.)*

Meeroff, J. C. (Mayo Clin., Rochester, Minn.). *Acta Gastroenterol. Latinoam.* 6(2):55-61, 1974.

The effects of metoclopramide on gastric acid secretion and the rate of gastric emptying in normal subjects and duodenal ulcer patients were studied. Metoclopramide (10, 20, and 40 mg) was injected i.v. into 30 normal subjects, 30 duodenal ulcer patients with intact stomachs, and 30 duodenal ulcer patients who had undergone truncal vagotomy and pyloroplasty; in some cases histamine phosphate (0.04 mg/kg) was injected s.c. simultaneously with the metoclopramide. The effects on basal acid output, histamine-augmented acid output, the rate of gastric emptying of an isotonic saline "test meal" (500 ml infused into the stomach *via* gastric tube), and serum gastrin concentration were determined. Metoclopramide had no effect on basal output or histamine-stimulated acid output in the normal controls or duodenal ulcer patients. Although it significantly increased the rate of gastric emptying in the controls and duodenal ulcer patients who had undergone truncal vagotomy and pyloroplasty, metoclopramide had no effect on acid secretion or serum gastrin. The effects on gastric emptying were significantly greater with 40 mg metoclopramide than with 10 mg. In doses of 10-20 mg, metoclopramide had no side effects, but 40 mg caused mild to moderate watery diarrhea, abdominal spasms, and, in 60% of the patients, drowsiness. The results indicate that in humans metoclopramide increases the rate of gastric emptying in both intact and vagotomized stomachs, that this effect is not related to the release of gastrin, that the mechanism of action is independent of the integrity of the vagus nerves, and that metoclopramide has no effect on gastric acid secretion.

5739 BLOOD SEROTONIN AND GLUCOSE LEVELS IN PATIENTS WITH DUMPING SYNDROME AFTER ORAL LOADING WITH 100 ML OF 50% GLUCOSE. *(Pol.)*

Schabowski, J.; Pokora, J. (Inst. Intern. Dis., Med. Acad., Lublin, Poland). *Pol. Tyg. Lek.* 30(4):141-144, 1975.

In 24 patients with dumping syndrome (19 men and 5 women, aged 21-67 yr) blood serotonin and glucose levels, blood pressure and pulse rate were determined in the fasting state, and also 15 min, 30 min, and 1-5 hr after p.o. administration of 50% glucose. A control group of 9 patients (aged 32-62 yr) without dumping syndrome was subjected to similar treatment. All subjects in both groups had previously undergone partial gastrectomy. Four different types of behavior with regard to blood serotonin and glucose levels were observed in patients with dumping syndrome: 11 patients (first type) showed a rise in serotonin concentration after the first 15 min with a considerable rise in glucose level followed by secondary hypoglycemia after 2-3 hr; 4 patients (second type) showed a rise in serotonin level after administration of glucose, while no significant changes occurred in the level of glucose; 5 patients (third type) showed a very high rise in glucose level followed by hypoglycemia after 2-3 hr, but without serotonin changes; and 4 patients (fourth type) showed no significant changes in serotonin and glucose levels as was also observed in controls.

5740 ROENTGENO-ENDOSCOPIC COMPARISONS IN DETERMINING THE PROXIMAL BOUNDARY OF CANCER OF THE STOMACH. *(Rus.)* Marmorshtein, S. Y.; Shnirelman, A. I.; Rozanov, Y. L.; Savinkin, Y. N. (P. A. Gertsen Moscow Sci. Res. Inst. Oncol., USSR). *Sov. Med.* (9):92-97, 1974.

STOMACH

Peptic Ulcers

5799 ELECTRICAL POTENTIAL DIFFERENCE, SODIUM ABSORPTION AND POTASSIUM SECRETION BY THE HUMAN RECTUM DURING CARBENOXOLONE THERAPY. *(E.)* Tomkins, A. M.; Edmonds, C. J. (Univ. Coll. Hosp., London, England). *Gut* 16(4):277-284, 1975.

The transmucosal electrical potential difference and sodium and potassium net fluxes were measured in patients on carbenoxolone therapy for peptic ulcer, and were compared to measurements in normal individuals. Of nine patients (aged 19-65 yr), six had gastric ulcer and three had duodenal ulcer; eight of these had no clinical evidence of disease. Each patient was studied before, during and after a 6-week course of carbenoxolone sodium (100 mg three times/day for 1 week, followed by 50 mg three times/day for 5 weeks). The ninth patient, a 62-yr-old man with gastric ulcer, developed fluid retention while on the drug, but remained in the experiment while in the hospital. Potential difference was measured with probe and skin electrodes. Flux measurements were obtained with dialysis tubes mounted on rubber catheters and containing 1.6 ml solution. There was a rise in transmucosal potential difference persisting throughout treatment in all subjects, accompanied by an increase in sodium absorption and potassium secretion. Comparison of the potential difference changes produced by carbenoxolone with those due to the mineralocorticoid 9-α-fluorocortisol (taken by the two controls) showed that carbenoxolone had about 0.001% the potency on a weight basis, and the two drugs appeared to be additive in their effects. Topical instillation of carbenoxolone produced an elevation of potential difference which persisted for 3 days. Amiloride and bendrofluazide did not interfere with these actions of carbenoxolone, but spironolactone abolished them. The patient with fluid retention and hypokalemia had a rectal potential difference similar to that of the other patients who had no side effects. It is concluded that carbenoxolone consistently produces mineralocorticoid activity in the rectal mucosa of all individuals taking the drug, and that this may reflect an inherent property of the drug.

5800 THE EFFECT OF INTRAVENOUS INFUSIONS OF PROSTAGLANDINS E_2 AND $F_{2\alpha}$ ON HUMAN GASTRIC FUNCTION. *(E.)* Newman, A.; de Moraes-Filho, J. P. P.; Philippakos, D.; Misiewicz, J. J. (Cent. Middlesex Hosp., London, England). *Gut* 16(4):272-276, 1975.

The effect of i.v. infusions of prostaglandins E_2 and $F_{2\alpha}$ at various dose levels on basal or on maximally or submaximally pentagastrin-stimulated acid secretion was studied in 40 male subjects with peptic ulcer, x-ray negative dyspepsia, or no gastrointestinal disease. Each received a continuous i.v. infusion of either 0.15 M saline, pentagastrin or prostaglandins. Prostaglandin $F_{2\alpha}$ (0.08 µg/kg/min) transiently, but significantly, inhibited submaximal acid output and increased the frequency of antral contractions. Prostaglandin E_2 (0.08 µg/kg/min) inhibited basal acid secretion. It is concluded that the inhibition of acid secretion by prostaglandin $F_{2\alpha}$ is of interest in emphasizing the species differences in responses to this agent. Further, additional studies of antral contractibility in individuals with more active antral contractions are indicated, since in these persons, only infrequent contractions were observed in the basal state, averaging 1/min.

5801 THE EFFECT OF DIAZEPAM ON PENTAGASTRIN-STIMULATED AND NOCTURNAL (SLEEPING) GASTRIC SECRETION IN MAN. *(E.)* Roberts, D. M.; Oldrey, T. B. N. (R. Army Med. Coll., London, England). *Am. J. Gastroenterol.* 63(5):396-399, 1975.

The effects of diazepam on stimulated gastric secretion and on unstimulated nocturnal secretion during sleep were studied in 10 male patients with dyspepsia (six with duodenal ulcer). Gastric secretion was measured for 3 hr following an s.c. injection of pentagastrin (6 µg/kg), an i.v. injection of diazepam (10 mg), and/or an i.v. injection of atropine (1.2 mg). Gastric secretion was also measured for 7 hr during confirmed nocturnal sleep that was preceded in some cases by an i.v. injection of diazepam (10 mg). The mean acid output after pentagastrin alone was 25.96, 13.00, and 5.61 mM HCl in the 1st, 2nd, and 3rd hr, resp. The addition of diazepam to pentagastrin resulted in a significant reduction in acid output during the 2nd (52.6% reduction) and 3rd (75.0% reduction) hr. The further addition of atropine resulted in a further reduction of 31.4% in the 1st hr, 42.0% in the 2nd hr, and 76.4% in the 3rd hr. The effects of diazepam and atropine on the pentagastrin-induced volume output were similar. The mean unstimulated nocturnal acid secretion over 7 hr was 24.83 mM HCl and the mean volume output was 338 ml. Diazepam did not significantly alter these parameters. The results suggest that diazepam acts during wakefulness by inhibiting secretory stimuli arising centrally, thus providing a rationale for use of this drug in patients with peptic ulcer in whom stress may be a pathogenic factor.

5802 GASTRO-OESOPHAGEAL REFLUX COMPLICATING HIGHLY SELECTIVE VAGOTOMY. *(E.)* Temple, J. G.; McFarland, J. (R. South. Hosp., Liverpool, England). *Br. Med. J.* 2(5964):168-169, 1975.

Patients with chronic duodenal ulceration and no evidence of pyloric stenosis, gastroesophageal reflux, or hiatus hernia underwent highly selective vagotomy. Of 20 patients, five (three men and two women, aged 41-56 yr) developed persistent symptoms of gastroesophageal reflux, with the usual features of heartburn, retrosternal discomfort and regurgitation accompanied by increased flatulence. This complication developed shortly after surgery in three patients and between 6 and 12 months in the remaining two. Postoperative barium meal examination showed gastroesophageal reflux in four patients, with evidence of hiatus hernia in three. All these patients showed normal gastric emptying after the barium meal. All required constant medication for their discomfort and all were classified as grade III on the Visick scale. The insulin test was positive in four of these patients. It is suggested that as a result of the greater mobilization of the stomach which is necessary in highly selective vagotomy, a degree of gravitational dependence develops which may alter slightly the angle of entry of the esophagus into the stomach. Since making the observations in these five cases, a practice has been instituted of narrowing the angle of His by opposing the stomach to the esophagus with a continuous chromic catgut stitch run up for about 5 cm from the esophagogastric junction. This simple procedure may readily be added when small vagal fibers are being cleared from the area.

5803 EFFECT OF THERAPEUTIC DOSES OF ULTRASOUND ON VASCULAR PERMEABILITY OF THE GASTRIC MUSOSA IN PATIENTS WITH PEPTIC ULCERS. *(Rus.)* Nikitin, G. A. (Smolensk Med. Inst., USSR). *Sov. Med.* (2):53-56, 1975.

5860 MECKEL'S DIVERTICULUM. SHOULD IT BE EXCISED INCIDENTALLY AT OPERATION? *(E.)* Michas, C. A.; Cohen, S. E.; Wolfman, Jr., E. F. (Dep. Surg., Univ. California, Davis). *Am. J. Surg.* 129(6):682-685, 1975.

During a 7-yr period, 35 cases of Meckel's diverticulum were recorded, 33 discovered at operation and two at autopsy. Of the 33 found at operation, 21 were found incidentally during surgery for other diseases, and 12 represented the primary source of the signs or symptoms for which celiotomy was performed. In the series presented here, there were 18 males and 17 females (aged 7 weeks to 77 yr), with the highest incidence during the second decade. Of 12 patients with signs or symptoms resulting from complications of a Meckel's diverticulum, four presented with hemochezia varying from passage of bright red blood to passage of tarry feces. Gastric mucosa was present in the diverticulum in three of these patients, and ileal mucosa was found in the fourth. Abdominal pain was the primary symptom in four other patients, each of whom was found to have acute Meckel's diverticulitis, with or without perforation. The remaining four had small bowel obstruction secondary to either intussusception or an adhesive band. Of the 33 diverticula, 31 were removed at operation. There were no operative deaths. The major complications reported in the literature for Meckel's diverticulum are hemorrhage, obstruction, inflammation, and benign and malignant neoplasia. Hemorrhage is most frequent in children, while inflammation is most common in adults. Because complications of a Meckel's diverticulum occur in 15-33% of cases and invariably require operative treatment, and because when signs or symptoms arise, morbidity and mortality are high, it is suggested that incidental Meckel's diverticulectomy be performed at any age when the morbidity and mortality of the primary procedure will not thus be substantially increased.

5861 ANTIPERISTALTIC ILEAL SEGMENT IN THE PREVENTION OF ILEOSTOMY DIARRHEA. *(E.)* Cohen, S. E.; Matolo, N. M.; Michas, C. A.; Wolfman, Jr., E. F. (Univ. California Sch. Med., Davis). *Arch. Surg.* 110(7):829-832, 1975.

An antiperistaltic segment was created in 5 of 10 ileostomized dogs to investigate its value in prevention of ileostomy diarrhea. All 10 had the terminal part of the ileum divided about 5 cm from the ileocecal valve, the distal end oversown, and the proximal end exteriorized. In 5 dogs a 4-cm antiperistaltic ileal segment was placed 30.5 cm proximal to the ileostomy. The antiperistaltic segments were removed after 3 weeks, and the intestinal continuity restored. Daily preoperative (5 days) and postoperative determinations were made of body weight and serum and urine electrolyte values (sodium and potassium). Ileostomy drainage was also calculated. Following surgery, the dogs given the ileostomy only lost about 20% of their body weight, and serum sodium decreased by 12-30 mEq/liter. Potassium remained normal. All 5 died between 2-9 days postoperatively of massive water and electrolyte imbalance. The dogs given ileostomy and an antiperistaltic segment lost less than 10% of their body weight, and serum sodium remained normal. The stools became nonwatery, and roentgenography showed greatly prolonged transit time (2 hr 45 min) in contrast to the controls (50 min). After removal of the antiperistaltic segment, the dogs lost an additional 10-15% of their body weight, serum sodium level showed a mean decrease of 15 mEq/liter, and transit time shortened to one hr and 15 min. Two of the 5 subsequently died of water and electrolyte imbalance. It is concluded that inclusion of an antiperistaltic segment can successfully control ileostomy diarrhea.

5862 SMALL-BOWEL OBSTRUCTION SECONDARY TO ENDOMETRIOSIS. *(E.)* Martimbeau, P. W.; Pratt, J. H.; Gaffey, T. A. (Mayo Grad. Sch. Med., Univ. Minn., Rochester). *Mayo Clin. Proc.* 50(5):239-243, 1975.

A review of Mayo Clinic records (1950-1970) disclosed 11 cases of intestinal obstruction due to endometriosis of the small bowel. The endometriosis involved the ileum in all 11 cases and was not found proximal to the ileum in any case; it was necessary to resect a portion of the small intestine in all cases. The ileal endometriosis was restricted to the serosa and the muscular coats, and the obstruction was due to fibrosis and kinking of the bowel. Because the symptoms are not acute or specific, the diagnosis is seldom established prior to laparotomy. If pelvic endometriosis is minimal, intestinal resection is adequate; but if the pelvic lesions are extensive, or if multiple sites in the intestines are involved, then more radical resection and bilateral oophorectomy are indicated.

5863 INTRALUMINAL DUODENAL DIVERTICULUM: REPORT OF TWO CASES AND REVIEW OF THE LITERATURE. *(E.)* Fleming, C. R.; Newcomer, A. D.; Stephens, D. H.; Carlson, H. C. (Mayo Grad. Sch. Med., Univ. Minn., Rochester). *Mayo Clin. Proc.* 50(5):244-248, 1975.

Because of the rarity of intraluminal duodenal diverticulum, 2 cases are presented along with a review of the literature on the subject. In both cases described, a roentgenogram of the upper gastrointestinal tract showed an intraluminal duodenal diverticulum in the 2nd portion of the duodenum. As of 1972, there were approximately 33 reported cases of intraluminal duodenal diverticulum; 29 of the 33 patients were adults. Most patients presented with abdominal pain and obstructive symptoms; gastrointestinal bleeding had occurred in 25%. Barium study showed a characteristic radiolucent halo that represented the wall of the diverticulum. It is suggested that surgery be approached with caution because of possible injury to the papilla, and in children, coexisting congenital anomalies may be present; in general, surgical intervention should be reserved for patients who have severe, persisting symptoms.

5864 GALLSTONE ILEUS: REVIEW OF THE LITERATURE AND PRESENTATION OF THIRTY-FOUR CASES.

(E.) Day, E. A.; Marks, C. (Louisiana State Univ. Sch. Med., New Orleans). *Am. J. Surg.* 129(5):552-558, 1975.

An analysis of 34 patients (31 women and 3 men, aged 37-93 yr) with gallstone ileus is presented with a review of the literature on the subject. A history of biliary disease was present in 13 of the 34 patients. Surgical treatment was carried out in 32 patients, with an operative mortality of 19%; enterotomy alone had a mortality of 14%. Only 3 of 32 patients who underwent operation had recurrent symptoms of biliary disease. Two patients in the series of 34 developed carcinoma of the gallbladder. All 3 patients who underwent one-stage cholecystectomy, fistula repair, and enterotomy survived. Those 3 cases added to 23 previously reported offer validity to one-stage repair in dealing with the entire disease process during one operative procedure, thus eliminating the high morbidity after enterotomy alone.

5865 LUMENAL AND MEMBRANE HYDROLYSIS OF STARCH IN SOME DISEASES OF THE SMALL INTESTINE AND PANCREAS.

(E.) Masevitch, C. H.; Ugolev, A. M.; Zabelinskii, E. K.; Kisily, N. P. (Leningrad Med. Inst. Hyg. Sanit., USSR). *Am. J. Gastroenterol.* 63(4):299-306, 1975.

α-Amylase and γ-amylase levels were determined in a study of lumenal and membrane hydrolysis of starch. A total of 143 subjects were studied: 28 normal; 24 with nontropical sprue; 81 with chronic proximal enteritis; 10 with chronic pancreatitis. Mucosal samples of small intestine were aspirated and prepared for both morphological and enzymatic studies. A dependence was observed between the characteristics of the membrane hydrolysis of starch and the degree of morphological disturbances of the intestinal mucosa. The maximal decrease of the binding properties of the intestinal epithelium and γ-amylase of homogenate was found in subtotal atrophy of mucosa. In chronic jejunitis without atrophy the degree of disturbance of the membrane hydrolysis was minimal. An intermediate degree of disturbance was observed in partial atrophy of mucosa. In patients with chronic pancreatitis, α-amylase activity in the lumen of jejunum decreased 75-80%. The characteristics of the membrane digestion of starch were correlated with the morphological pattern of mucosa; the degree of lumenal hydrolysis of starch was approximately normal, with the exception of a decrease in 6 patients. The results suggest that the lumenal and membrane hydrolysis form an integrated system within the limits of which mutual compensation of deficiencies is possible.

5866 VITAMIN B_{12} ABSORPTION IN PATIENTS WITH CONTINENT ILEOSTOMY.

(E.) Jagenburg, R.; Kock, N. G.; Philipson, B. (Sahlgrenska Hosp., Goteborg, Sweden). *Scand. J. Gastroenterol.* 16(1):141-144, 1975.

Vitamin B_{12} absorption was studied in 16 men and 18 women 10 months to 6 yr after construction of a continent ileostomy. The mean age of the patients at the time of study was 33 yr, and none had been treated with vitamin B_{12}, folate, or iron after the operation. Schilling test values, serum vitamin B_{12}, serum folate, serum iron, total iron binding, capacity (TIBC) and hemoglobin were measured in all patients; in 3 patients, the local absorption of vitamin B_{12} from the ileal reservoir was measured. Normal Schilling test values were obtained in 21 patients after a single determination, and repeated tests showed a normal B_{12} absorption in 8 of the 13 patients in whom the Schilling test values were initially below 10%. In the remaining 5 patients, repeated Schilling tests showed borderline values (5-10%) in 4 cases and a low value (mean 4.5%) in 1 case. One of the patients with borderline values had previously undergone resection of 80 cm of the terminal ileum. In all but 1 patient, the serum iron, TIBC, serum folate, and whole blood folate levels were normal. When radioactive vitamin B_{12} and intrinsic factor were instilled directly into the ileal reservoir, the recovery of radioactivity in the 24-hr urine samples varied from 1.6-6.9%, indicating that the vitamin was absorbed by the mucous membrane of the reservoir. The construction of a continent ileostomy reservoir does not, therefore, appear to expose the patient to an increased risk of developing vitamin B_{12} malabsorption.

5867 MUCOSAL MORPHOLOGY, BACTERIOLOGY, AND ABSORPTION IN INTRA-ABDOMINAL ILEOSTOMY RESERVOIR.

(E.) Philipson, B.; Brandberg, A.; Jagenbrug, R.; Kock, N. G.; Lager, I.; Ahren, C. (Sahlgrenska Hosp., Goteborg, Sweden). *Scand. J. Gastroenterol.* 16(1):145-153, 1975.

The mucosal morphology, microbial flora, and absorption from continent ileostomy reservoirs were studied in 6 patients provided with such reservoirs after undergoing proctocolectomy because of ulcerative colitis. The studies were performed 1-12 months and 2 yr after construction of the reservoir. Biopsies of the reservoir mucosa were examined by light and electron microscopy; serial dilutions of the reservoir contents were incubated with appropriate media under aerobic and anaerobic conditions; and the absorption of directly instilled test solution (containing L-phenyl-alanine, D-xylose, and phenolsulfonaphthalein) from the reservoir was measured. The results indicated that the mucous membrane of the terminal ileal segment used for construction of the reservoir underwent morphological changes characterized by an increased cell turnover and shortening of the villi; these changes were noted within 1 month after the operation, and there was no evidence for a continuously progressing process. The brush border was intact in all specimens and no cellular lesions were discovered. The number of microorganisms/g of reservoir contents varied between 10^4 and 10^{8-9}. In 19 of the 26 samples the anaerobes outnumbered the aerobes, and in 5 specimens, equal numbers of aerobes and anaerobes were found. *Escherichia coli* and *Streptococcus faecalis* were isolated from all samples, and lactobacilli, bacteroides, and *Clostridium perfringens* were isolated at least once from 5 of the 6 patients. In spite of the new microbial ecology and morphological changes, the reservoir mucous membrane did not retain an absorptive capacity for D-xylose and phenylalanine.

5868 TRUE VILLOUS ADENOMA OF THE JEJUNUM. *(E.)* Delevett, A. F.; Cuello, R. (Bridgeport Hosp., Conn.). *Gastroenterology* 69(1):217-219, 1975.

A 73-yr-old female presented with intermittent abdominal pain, anorexia, weight loss, and a positive stool hematest. An intraluminal defect in the middle portion of the ascending colon was noted. At operation, a fungating tumor in the ascending colon was found. A portion of terminal ileum, the cecum, and ascending colon was resected and an ileotransverse colostomy was performed. Pathological study showed an adenocarcinoma of the colon with negative regional nodes. Fifteen months later the patient experienced five attacks of constant midabdominal pain and vomited large quantities of greenish fluid which relieved the attacks. Examination revealed intussusception of the jejunum and a tumor mass at the distal end of the intussuscepting bowel. Operation revealed no evidence of recurrent tumor. On opening the jejunum, a soft, thickened, markedly hypertrophic mucosa with definite demarcation from the normal bowel was noted. Part of the jejunum was resected. Studies showed the tumor to be a hyperplastic proliferating adenomatous lesion with a villous pattern, consisting of tall columnar epithelium suspended in long cords of loosely arranged fibrous connective tissue. There was no evidence of atypia or of infiltration of the underlying stroma. This patient demonstrated the typical gross and microscopic characteristics of a villous adenoma.

Malabsorption

5901 LEUKOCYTE REACTIVITY TO α-GLIADIN IN DERMATITIS HERPETIFORMIS AND ADULT COELIAC DISEASE. *(E.)* Allardyce, R. A.; Shearman, D. J. C. (Univ. Dep. Ther., Edinburgh, Scotland). *Int. Arch. Allergy Appl. Immunol.* 48(3):395-400, 1975.

The leukocyte adherence inhibition test was used to study leukocyte reactivity to α-gliadin in 20 patients with dermatitis herpetiformis, and in 11 patients with adult celiac disease. Sedimented peripheral blood leukocytes from patients and normal subjects were washed twice in Hepes-buffered essential medium containing Hank's salts, and incubated in plastic tubes with 100 μg of purified α-gliadin at a concentration of 2 x 10^7 cells/ml. Control preparations were incubated without antigen. Following incubation for 30 min at 37 C, the test and control cells from each individual were placed on opposite sides of duplicate non-mirrored surfaces. After further incubation for 1 hr at 37 C in a moist atmosphere, the cells were counted. The coverslips were removed, and the non-adherent cells were removed. After a drop of fresh medium was placed on the surface, the remaining adherent cells were counted. The percent adherence of cells from the controls and test slides of each surface was calculated, and the mean of duplicate readings was recorded. The percent inhibition of leukocyte adherence equals 100 times the mean test adherence over the mean control adherence. Leukocytes from both groups of patients showed a significant inhibition of leukocyte adherence. Possible cell-mediated reactivity to this fraction of gluten is suggested.

5902 THE UPTAKE OF VITAMIN B_{12} BY THE SEDIMENT OF JEJUNAL CONTENTS IN PATIENTS WITH THE BLIND-LOOP SYNDROME.

(E.) Schjonsby, H.; Hofstad, T. (Med. Dep. A, Gade Inst., Univ. Bergen, Norway). *Scand. J. Gastroenterol.* 10(3):305-309, 1975.

Whether the sediment of jejunal contents in patients with the blind-loop syndrome was able to take up intrinsic factor-bound vitamin B_{12}, and whether such uptake prevented the intestinal absorption of the vitamin, was studied. Following preincubation of intrinsic factor-bound $^{57}CoB_{12}$ with the jejunal sediments of six patients with the blind-loop syndrome, the mean uptake by the sediments of intrinsic factor-bound $^{57}CoB_{12}$ (28.1%) was significantly higher than the mean uptake by jejunal sediments from five control patients (5.8%). The uptake by the sediments significantly decreased when the incubations were carried out in the presence of lincomycin and neomycin. The jejunal sediments from the patients with the blind-loop syndrome inhibited the uptake of intrinsic factor-bound $^{57}CoB_{12}$ by perfused rat intestinal segments, whereas the sediments from controls had no such inhibitory effects. The results indicate that uptake by intestinal bacteria of intrinsic factor-bound vitamin B_{12} may contribute to the malabsorption of the vitamin in patients with the blind-loop syndrome, since the B_{12}-intrinsic factor complex is unavailable for intestinal absorption when it has been taken up by intestinal bacteria.

5903 MALABSORPTION AND PROTEIN-LOSING ENTEROPATHY IN A CHILD WITH X-LINKED AGAMMAGLOBULINEMIA.

(E.) Norman, M. E.; Hansell, J. R.; Holtzapple, P. G.; Parks, J. S.; Waldmann, T. A. (Child. Hosp. Philadelphia, Pennsylvania). *Clin. Immunol. Immunopathol.* 4(2):157-164, 1975.

A patient with infantile x-linked agammaglobulinemia was studied for malabsorption and protein-losing enteropathy. He first presented for hospitalization at 3 yr of age with severe hypogammaglobulinemia, a nonbloody diarrhea, vomiting, and arthralgia. Otitis media and sinusitis were present and treated with ampicillin. The patient showed failure to thrive over the next 30 months with intermittent diarrhea and anorexia. At 6 yr of age, diarrhea and weight loss became more severe despite gamma globulin therapy, but plasma therapy caused a temporary remission. At 7 1/2 yr, hypocalcemic tetany developed and malabsorption secondary to gluten enteropathy was diagnosed. Gluten-free diet caused a temporary remission. At 8 1/2 yr, radiography revealed thickening of the mucosal folds of the upper small bowel, and segmentation of the barium. Biopsy showed slightly flattened villi and inflammatory cells in the lamina propria. Functional hypoparathyroidism secondary to hypomagnesemia was later diagnosed, and magnesium therapy controlled the tetany. At 10 yr, an episode of severe hypoprothrombinemia occurred and the malabsorption syndrome was reevaluated. For protein metabolic studies, ^{51}Cr-albumin and ^{125}I-IgG were given i.v. at 14 and 13 μCi, resp., and 24 hr urine and stool collections were made from days 1-7. Immunologic studies involved measurement of immunoglobulins G, M, A and E and of CH50 hemolytic and C_3 complements. Delayed hypersensitivity skin tests were performed and an *in vitro* assay of cellular immunity was carried out. The labelled IgG had a half-life of 9.0 days and showed a fractional catabolic rate of 17.9%. Actual plasma loss was about 58.8 ml/day based on the ^{51}Cr-albumin, significantly higher than normal. Immunoglobulin levels wer markedly reduced (IgG: 48-100, IgA: 0-5, IgM: 0-9 mg/10 ml, and IgE: 4 ng/ml); C_3 complement was slightly reduc (86 mg/100 ml). Delayed hypersensitivity testing showe normal response to *Candida* antigen, implying intact cellular immunity. It is concluded that malabsorption and protein-losing enteropathy were both present in a child with infantile x-linked agammaglobulinemia, leading to marked abnormality in gamma globulin metabolism.

5904 PROTEIN-LOSING ENTEROPATHY AND MALABSORPTION IN ACUTE MEASLES ENTERITIS.

(E.) Dossetor, J. F. B.; Whittle, H. C. (Ahmadu Bello Univ. Hosp., Zaria, Nigeria). *Br. Med. J.* 2:592-593, 1975.

The association of measles and malnutrition was studied in 28 children with acute measles accompanied by diarrhea. Fecal protein loss, urine protein, and lactose tolerance were determined, and 1-hr blood xylose tests were performed. ^{59}Fe-labeled iron dextran (0.1 μCi/kg) was injected i.v.; all stools were collected for three days and plasma was sampled daily. Mean fecal ^{59}Fe-dextran clearance of 5 patients in the acute stage was 5.7% of plasma volume/day. After recovery, clearance fell to 1.49%. Absolute albumin loss was 1.68 g/day. Mean urine protein loss in 22 patients in the acute stage was 350 mg/liter, most of which was albumin. None showed urinary protein on recovery. Of 17 patients tested for lactose intolerance, 4 were intolerant. One died; the others were tolerant on retesting. Blood glucose rose more than 1.67 mM/liter in 11 and rose 1.11-1.67 mM/liter in 5. Two of the latter died.

In 1 patient, blood glucose did not rise during illness but rose 1.17 mM/liter on recovery. Xylose absorption tests showed a mean acute level of 0.93 mM/liter and a recovery level of 1.71. It is concluded that fecal protein loss and malabsorption may contribute significantly to malnutrition following measles.

5905 DERMATITIS HERPETIFORMIS AND SMALL INTESTINAL LESION - NO STRICT ASSOCIATION IN GERMAN PATIENTS.

(E.) Ruppin, H.; Weidner, F.; Domschke, S.; Domschke, W.; Classen, M.; Hornstein, O. P. (Dep. Med., Univ. Erlangen-Nurnberg, Germany). *Acta Hepatogastroenterol.* 22(2):105-111, 1975.

An investigation was conducted of morphological and functional characteristics of small intestinal mucosa in a group of 16 German patients with dermatitis herpetiformis (8 men and 8 women, aged 41-79 yr) and in healthy German controls living in the same Bavarian area of Erlangen-Nurnberg and its immediate vicinity. By stereomicroscopy, finger- or leaf-shaped villi were found exclusively both in patients and controls. Convoluted or flat mucosa could not be detected in dermatitis herpetiformis patients. Accordingly, in all cases, normal structure of jejunal mucosa without signs of mucosal or submucosal inflammation was demonstrated histologically. However, mean counts of interepithelial lymphocytes in dermatitis herpetiformis patients were slightly but significantly increased over controls. Intestinal disaccharidase activities were not statistically different from those of healthy control subjects, and oral lactose tolerance tests were normal in each of 8 patients tested. It is suggested that immunological and genetic differences between dermatitis herpetiformis patients reported in British and American papers and the patients studied in this report may be responsible for the basically differing results as to "dermatogenic enteropathy". Moreover, the mean ages of patients reported in other studies were about 19 to 26 yr below the mean age found in this study. It is suggested that the age of first manifestation and follow-up of dermatitis herpetiformis may also be important factors in the nature and frequency of intestinal involvement in dermatitis herpetiformis.

5906 PREGNANCY IN PATIENTS WITH COELIAC DISEASE.

(E.) Ogborn, A. D. R. (Hammersmith Hosp., London, England). *Br. J. Obstet. Gynaecol.* 82(4):293-296, 1975.

The effects of dietary management and supportive obstetric care on the course and outcome of pregnancies in patients with celiac disease were studied. Twenty-five women, who had previously gone through a total of 38 pregnancies, were placed on a strict gluten-free diet and given calcium gluconate twice daily (1.5 g, p.o.), vitamin B_{12} (1000 μg, i.m.) after 6, 20, and 34 weeks of gestation, and compound i.m. vitamins once weekly. Exacerbations of diarrhea were controlled by hospital rest, dietary supervision, and salicylazosulfapyridine or codeine phosphate as necessary. Progesterone status was monitored during the first 16 weeks and hydroxyprogesterone (250 mg twice weekly) given as indicated. Fetoplacental function was monitored during the third trimester and the fetus was closely monitored during labor. The perinatal mortality in patients on an unrestricted diet was 7%, 74% of the 38 pregnancies in women on unrestricted diets ending in the birth of a viable infant which survived the neonatal period. The perinatal mortality rate in the treated patients was 10%, 86% of the pregnancies in this group ending in the birth of a viable infant which survived the neonatal period. None of the babies had celiac disease. Although no significant differences were demonstrable between the treated and untreated groups, the apparent overall improvement in outcome of the pregnancies with dietary management and obstetric supervision was encouraging.

5907 IN VITRO PATHOGENETIC STUDIES OF COELIAC DISEASE: EFFECTS OF PROTEIN DIGESTS ON COELIAC INTESTINAL BIOPSY SPECIMENS MAINTAINED IN CULTURE FOR 48 HOURS.

(E.) Jos, J.; Lenoir, G.; de Ritis, G.; Rey, J. (Hosp. Enfants-Malades, Paris, France). *Scand. J. Gastroenterol.* 16(1):121-128, 1975.

The effects of various gliadin and casein digests on celiac intestinal biopsy specimens maintained in culture for 48 hr were studied. Biopsy specimens were taken at the duodeno-jejunal flexure from 11 control children, 24 children with treated celiac disease, and 20 children with untreated celiac disease. The specimens were incubated at 37 C for 48 hr in media containing antibiotics and, in some cases, various peptic-tryptic (PT) or peptic-tryptic-chymotryptic (PTC) digests of gliadin and casein. The specimens were examined immediately after excision and after 48 hr incubation by light and electron microscopy. The morphologic abnormalities in the surface epithelial cells in 11 of the 14 biopsy specimens from children with active celiac disease disappeared almost immediately during culture in the absence of gliadin digests. In flat biopsies cultured in the presence of the PT gliadin digest, epithelial restoration was inhibited and a cytotoxic effect was obvious; a similar effect was observed in the presence of the PTC gliadin digest and the autoclaved PT gliadin digest. The casein hydrolysates exerted a slight toxic effect which seemed to be reduced by autoclaving. In the control specimens and in 16 restored celiac biopsies from patients in remission, there was no or little change after culture in the presence of gliadin or casein digests. In 6 of 11 biopsy specimens taken from 8 patients in remission after gluten challenge, PT, autoclaved PT, and PTC gliadin digests all exerted an obvious cytotoxic effect; in most cases, no such effect was seen in the presence of the PT digest of casein. In all specimens studied, thorough PTC hydrolysis of gliadin abolished all of its *in vitro* toxic effects. The results suggest that the toxicity of gliadin is related to a relatively large peptide, which supports the hypothesis of a basic immune process.

LIBRARY

5908 MACROAMYLASEMIA ASSOCIATED WITH MALABSORPTION AND CRYOGLOBULINEMIA: CLINICAL AND BIOLOGICAL STUDY OF A NEW CASE. *(Fr.)* Touboul, J. P.; Hadchouel, P.; Hirsch-Marie, H.; Caroli, J.; Renault, H. (St. Antoine Hosp., Paris, France). *Med. Chir. Dig.* 3(6):419-426, 1974.

A new case of macroamylasemia associated with malabsorption and cryoglobulinemia was reported in a 33-yr-old woman with persistent and marked elevated amylasemia contrasted by normal amylasuria. The patient also suffered from severe weight loss (15 kg), asthenia, diarrhea and Raynaud's phenomenon. The macroamylase, demonstrated by serum electrophoresis and chromatography, was an amylase-IgA complex. Malabsorption, verified by various tests (quantitative analysis of fat in feces, induced hyperglycemia, lactose test, D-xylose test), may explain the anomalies observed in the hepatic picture (lowered cholesterol and lowered coagulation factors). Cryoglobulinemia, which was not involved in macroamylasemia, was due to the presence of IgA. Hematological results showed marked lymphoplasmocytic-type medullary infiltration. Although the patient did not exhibit classical dysglobulinemia, the coincidence of malabsorption and lymphoplasmocytic-type medullary infiltration might lead to the eventual appearance of a system disease. A review of the literature seems to indicate the relatively frequent association between IgA-macroamylasemia, malabsorption, alcoholism and pancreatitis.

5909 FOLLOW-UP STUDY OF PATIENTS WITH CELIAC DISEASE. *(Ger.)* Emons, D.; Bohm, E. R.; Rotthauwe, H. W. (Pediatr. Clin., Univ. Bonn, Germany). *Dtsch. Med. Wochenschr.* 99(38):1847-1853, 1974.

Follow-up examinations were performed on 25 children (ten boys and 15 girls) who had been given diet therapy for celiac disease diagnosed clinically before 3 yr of age on the basis of retarded development, distended abdomen, and pathologically loose stools (recurrent diarrhea in almost all cases, but abnormally bulky stools in only a few). In 13 cases the diagnosis was considered confirmed on the basis of abnormal xylose tests and prompt response to a gluten-free diet. Anemia, which often occurs in the first few weeks after institution of diet therapy, developed in 21. Life-threatening toxicosis occurred in four patients and was associated with hypoproteinemia and protein-deficiency edema in one. Cystic fibrosis was ruled out in all 25 children by the sweat test. Enteropathogenic bacteria were present initially or intercurrently in eight cases, and radiological examinations revealed the presence of functional gastrointestinal disorders in seven of the eight patients examined. Osteoporosis was radiologically diagnosed in seven children, but none had radiological or biochemical evidence of manifest rickets. At follow-up, villous atrophy was found on duodenal biopsies in 20 of these 25 children, and another patient developed marked villous atrophy 9 months after diet therapy was discontinued. The intestinal mucosa was completely normal in four cases. Patients with villous atrophy had eaten gluten-free diets for 6 months to 5 yr (mean 2 yr), and had eaten normal food for 9 months to 8 yr before biopsy. At follow-up, only one of these 21 patients had clinical and biochemical signs of a recurrence; although a long-term, gluten-free diet was prescribed, the parents failed to cooperate. Only three of these 21 children had to be treated for intestinal disorders when they started eating normal food. Clinical findings, hemoglobin levels, stool fat contents, and xylose test were normal on all but one of the 21 children with persistent villous atrophy at follow-up.

5910 TOTAL BODY POTASSIUM IN CHILDREN, WITH PARTICULAR REFERENCE TO COELIAC DISEASE. *(E.)* Boddy, K.; King, P. C.; Carswell, F. (Scottish Univ. Res. Reactor Cent., Glasgow). *Clin. Sci. Mol. Med.* 49(2):133-137, 1975.

Total body potassium was measured by whole-body counting in 20 children (11 males and nine females, 8 months to 13 yr and 10 months of age) with celiac disease and was compared with similar measurements in 20 children having diseases in which there was no clinical suspicion of electrolyte or water disturbance. The controls were matched as closely as possible with respect to sex, age, and height. All children were on a gluten-containing diet at the time of measurement. Total body potassium was estimated by detecting the 1.46 MeV gamma rays of ^{40}K, which is naturally radioactive and a constant fraction of natural body potassium. There was no significant difference between the measured values of total body potassium (in mM) in children with celiac disease and in control children or between males and females. At the clinical level, infantile celiac disease does not parallel malnutrition with respect to body potassium; potassium deficiency is not a complication of this disease. It is suggested that the potassium deficiency in malnutrition is a direct result of dietary factors. Apparently, in celiac disease, the potassium presented for absorption is evidently handled normally or there is compensatory retention by the body to accomodate abnormalities in absorption, giving a long-term normal balance.

LARGE INTESTINE

5927 SOCIAL CLASS DIFFERENCES AMONG PATIENTS WITH LARGE-BOWEL CANCER IN CALI, COLOMBIA. *(E.)* Haenszel, W.; Correa, P.; Cuello, C. (Natl. Cancer Inst., Bethesda, Md.). *J. Natl. Cancer Inst.* 54(5):1031-1035, 1975.

Social class differences associated with risk of large-intestine cancer were studied based on data from a population-based cancer registry in Cali, Colombia. The analysis covered 214 newly diagnosed cases of adenocarcinoma of the large intestine registered among residents of Cali between 1962-1971. Findings on social class differences in the prevalence of intestinal polyps in 404 autopsies among Cali residents were also included, and measurements were made on fresh colon specimens taken from 4 persons dying from accidental causes to examine the relation between tissue at risk and cancer incidence by segment. The risk of large-intestine cancer in males and females of all ages was higher for persons in the upper and middle socioeconomic classes than for those of the two lower socioeconomic classes. Risk of cancer of the stomach and uterine cervix was inversely related to social class. The socioeconomic gradients associated with risk of large bowel cancer were most marked for cancer of the ascending and rectosigmoid colon and were minimal for cancer of the cecum and rectum. These data present several parallels with information derived from comparisons of developed and developing countries and also appear consistent with recent information on the possible role of dietary factors in intestinal cancer. It is likely that strong associations between specific dietary items and income facilitated the detection of a socioeconomic gradient for large-intestine cancer in Cali.

5928 GUT BACTERIA AND THEIR METABOLIC ACTIVITIES IN FAMILIAL POLYPOSIS.

(E.) Bone, E.; Drasar, B. S.; Hill, M. J. (Cent. Public Health Lab., London, England). *Lancet* 1(7916):1117-1120, 1975.

Early work suggested that patients with cancer of the large intestine carry clostridia capable of dehydrogenating the steroid nucleus and also have high fecal bile-acid concentrations. Therefore, colonic environmental factors were investigated in familial polyposis, a disease predisposing to colorectal cancer. Samples of rectal contents and urine were obtained from 6 affected children of polyposis patients, 13 unaffected children of polyposis patients, 27 polyposis patients who had been treated by colectomy and ileorectal anastomosis, 11 ulcerative colitis patients treated by colectomy and ileorectal anastomosis, 8 patients treated for colonic carcinoma by partial colectomy and anastomosis, and 3 patients with benign polyposis syndromes not thought to predispose to malignancy. Although a high proportion of the affected and unaffected children of polyposis patients carried clostridia able to dehydrogenate the steroid nucleus, their average rectal bile-acid concentration was low. In addition, the bile acids were in many cases poorly degraded and were characterized by the presence of chenodeoxycholic acid; in 11 of these patients, including half of the unaffected children, less than 25% of the fecal cholesterol had undergone conversion to coprostanol or coprostanone by the gut flora, although these flora were able to degrade cholesterol *in vitro*. In the treated polyposis patients, rectal bile-acid and neutral-steroid concentrations were low and the cholesterol was virtually undegraded; the cholesterol had undergone some degradation in all of the ulcerative colitis patients who had undergone similar treatment. The results suggest that the inability of the polyposis patients and their unaffected children to degrade cholesterol in the intestine was due to unfavorable conditions in the intestine, a hypothesis that is favored by the lack of cyclic secondary amines in the urine of these persons (these amines are also synthesized by bacteria in the gut). If the unaffected children who were not able to degrade cholesterol later develop polyposis, the degradation of cholesterol by the gut flora would appear to be a simple diagnostic test for persons at high risk of developing polyposis.

5929 PNEUMATOSIS CYSTOIDES INTESTINALIS: TREATMENT WITH OXYGEN VIA CLOSE-FITTING MASK.

(E.) Simon, N. M.; Nyman, K. E.; Divertie, M. B.; Rovelstad, R. A.; King, J. E. (Mayo Clin., Rochester, Minn.). *JAMA* 231(13):1354-1356, 1975.

Treatment of four patients (2 men and 2 women, aged 64-69 yr) suffering from pneumatosis cystoides intestinalis with oxygen via a close-fitting mask is described. Symptoms included frequent, watery bowel movements, rectal bleeding, flatulence, and abdominal pain. The patients were treated with 70% oxygen administered by close-fitting mask for 5-8 days, after which all symptoms ceased and proctoscopic and barium-contrast roentgenographic findings in the colon were normal. Six months after oxygen treatment, one woman developed slight rectal bleeding which was confirmed as pneumatosis cystoides intestinalis in the rectosigmoid. The patient again responded favorably to oxygen therapy. Although pulmonary damage may result from oxygen exposure, even in patients with normal lungs, prompt withdrawal of oxygen therapy is generally effective in restoring normal pulmonary function within 1-2 days. In the absence of major disturbances of ventilation and perfusion, intermittent administration of 70% oxygen via close-fitting mask should be capable of increasing the nitrogen gradient between a closed space and capillary blood to a degree sufficient to ensure rapid diffusion from one to the other. During daytime meals and at other brief intervals, nasal cannulas may be used to deliver oxygen at 3-4 liters/min. On a program of this kind, with monitoring of vital capacity, the possibility of toxic effects from oxygen is greatly diminished, while the therapeutic needs of the patient can be met effectively. Oxygen treatment can be justified only for patients who have the symptomatic form of pneumatosis cystoides intestinalis and follow-up of patients treated in this manner is indicated.

5930 THE SPECTRUM OF COLITIS ASSOCIATED WITH LINOMYCIN AND CLINDAMYCIN THERAPY.

(E.) Le Frock, J. L.; Klainer, A. S.; Chen, S.; Gainer, R. B.; Omar, M.; Anderson, W. (West Virginia Univ. Med. Cent. Hosp., Morgantown). *J. Infect. Dis.* 131(Suppl):108-115, 1975.

The clinical, laboratory, sigmodoscopic, x-ray, and biopsy findings in 10 patients (7 women and 3 men, aged 22-70 yr) who developed colitis after lincomycin or clindamycin therapy are reported. Prior to antibiotic therapy in standard dosages, none of the patients had prior histories suggestive of preexisting bowel disease. An abrupt onset of diarrhea, crampy abdominal pain, fever, and leukocytosis was observed 1-12 days after discontinuation of the drug. Proctoscopic examination revealed erythematous friable mucosa covered with small raised, yellowish-white plaques that were sometimes confluent. Barium contrast studies of the colon demonstrated irregular, shaggy mucosa, ulcerations, cobblestone appearances, and thumb printing. Rectal biopsy showed acute inflammation with pseudomembranes with focal or superficial ulcerations. The clinical course lasted an average of 4 weeks, although all 10 patients recovered with supportive management consisting of administration of parenteral fluids and electrolytes supplemented with albumin. Antibiotic therapy in such cases is contraindicated unless secondary infection is present, and adrenocorticotropin hormone and steroids appeared to be of little value in modifying the course of the disease. Follow-up barium enemas and proctoscopy were done on all patients after supportive treatment and were normal. A history of diarrhea, fever, and mucosal changes seen on proctoscopy in a patient who has recently received clindamycin or lincomycin should raise the possibility of therapy-associated colitis, and clindamycin should be used only when indicated in serious infections.

5931 THE DETECTION OF ABERRANT DNA SYNTHESIS IN A MEMBER OF A HIGH-RISK CANCER FAMILY.

(E.) Deschner, E. E.; Long, F. C.; Katz, S. (Mem. Sloan-Kettering Cancer Cent., New York, N.Y.). *Am. J. Dig. Dis.* 20(5):418-424, 1975.

Examination of 4 siblings of a patient with multiple polyposis was performed with radiological, sigmoidoscopic, cytologic, and isotopic labeling procedures for the possible presence of colonic polyps. The patients, 3 men and 1 woman, were all over 40 yr of age. Polyps were absent on films as well as on endoscopy, and colonic cytologies of all 4 subjects were within normal limits. However, isotopic incorporation studies revealed the presence of an abnormal labeling pattern in some crypts of the biopsy incubated with tritiated thymidine of 1 family member. Along with normal crypts with label in the lower 2/3 of the colonic crypts, many crypts had cells labeled at the surface. Some of the surface cells removed by colonic wash were also isotopically labeled; thus, a defect in the regulation of colonic epithelial cell replication was found. The results suggest that in patients where such positive findings arise, periodic and intensive examinations should be performed, preferably by colonoscopy, to aid in the early detection of colon cancer.

5932 APPEARANCE AND GROWTH OF EARLY CARCINOMAS OF THE COLON-RECTUM.

(E.) Ekelund, G.; Lindstrom, C.; Rosengren, J.-E. (Dep. Surg., Univ. Lund, Malmo, Sweden). *Acta Radiol.* [*Diagn.*] *(Stokh.)* 15(6):670-679, 1974.

A series of 30 patients with carcinoma of the colon-rectum was examined in retrospect for preceding signs of polypoid lesions at the site where a carcinoma had later been diagnosed. Repeated double contrast roentgenography had been used routinely for examinations of the colon during a mean observation time of 5 yr. When first demonstrated, all but 4 of the polypoid tumors had at least 1 roentgenographic sign of malignancy. The mean linear growth rate was 0.61 mm/month. The 5-yr survival rate was 57%. Metastases were found in 19 cases. The results suggest that tumors with roentgenographic appearance of malignancy should be removed as soon as possible and that careful observation with repeated roentgenography is imperative in the absence of malignant signs.

5933 PREOPERATIVE RADIOTHERAPY FOR COLORECTAL CANCER.

(E.) Higgins, Jr., G. A.; Conn, J. H.; Jordan, Jr., P. H.; Humphrey, E. W.; Roswit, B.; Keehn, R. J. (VA Surg. Adjuvant Group, Washington, D.C.). *Ann. Surg.* 181(5):624-631, 1975.

In a prospective randomized trial, 700 patients with a confirmed histologic diagnosis of adenocarcinoma of the rectum or rectosigmoid were randomized to receive radiotherapy (2000-2500 rads in two weeks) prior to operation or to receive surgery alone. Five-year observed survival in the 453 patients on whom "curative" resection was possible was 48.5% in the x-ray treated group, compared with 38.8% in those who underwent surgery alone. In the 305 patients having low lying lesions which required abdominoperineal resection, survival in the group treated with x-ray was 46.9% compared with 34.3% in those who underwent surgery alone. Although these figures suggest a treatment benefit gained from the use of x-ray with surgery, neither figure is considered statistically significant. Histologically positive lymph nodes were found in 41.2% of the surgery only group but in only 27.8% of those patients receiving radiotherapy. Review of all patients who died during the study shows a consistently lower death rate from cancer in the radiotherapy group. Further studies are in progress to determine the optimal dose regimen.

5934 CARCINOID TUMOUR AND CROHN'S DISEASE.

(E.) Tehrani, M. A.; Carfrae, D. C. (West. Infirm., Glasgow, Scotland), *Br. J. Clin. Pract.* 29(5):123-124, 1975.

A case of Crohn's disease is reported in which carcinoid tumor was an incidental finding on pathological examination of the resected small bowel. A tiny focus of carcinoid tumor (3-4 cells) was present in histological sections of the terminal ileum. Reexamination of the gross specimen demonstrated seven small yellow mucosal plaques in the terminal 30 cm of the small intestine. Sections confirmed the presence of multiple mucosal and subsequent mucosal deposits of carcinoid tumor, with no extension of the tumor through the bowel wall. A marked focal increase in argentaffin-cells was noted in the resected specimen. Only one previous case of carcinoid tumor coexisting with Crohn's disease has been reported in the literature. Although it is unlikely that a true relation exists between regional enteritis and carcinoid tumor other than the long-accepted association of malignancy and chronic inflammation, the possibility of coexistence should be kept in mind by both the clinician and the pathologist.

5935 VARIATIONS IN CARCINOEMBRYONIC ANTIGEN LOCALIZATION IN TUMORS OF THE COLON.

(E.) Rogalsky, V. Y. (P. A. Herzen Res. Inst. Oncol., Moscow, USSR). *J. Natl. Cancer Inst.* 54(5):1061-1071, 1975.

The localization of carcinoembryonic antigen (CEA) in 78 tumors of the human colon was studied using antibody to CEA in an indirect Coons test. Morphologically it was possible to divide the neoplasms into two types: tissues in which CEA was localized in cells, and tissues in which malignant cells secreted CEA in greater or lesser quantity. In the first type of tissue, five forms of cells were noted: goblet-like, small vacuolar, limbic, those with intracellular accumulation of antigen, and diffuse. Tumor tissue secreting CEA could also be divided into 5 forms: holocrine-like, aprocrine-like, intraglandular, apical-basal, and lacunar-infiltrative. Thus, this study demonstrated that in malignant tissue there is a change in CEA localization as compared with that in cells of corresponding normal tissue. Several variations of CEA localization were observed. Tumor cells were found capable of secreting considerable amounts of this component. The change of antigen localization in the cell or its secretion was named antigenic translocation by the author.

5936 CHEMOTHERAPY AS AN ADJUVANT TO SURGERY FOR COLORECTAL CANCER.

(E.) Lawrence, Jr., W.; Terz, J. J.; Horsley, III, S.; Donaldson, M.; Lovett, W. L.; Brown, P. W.; Ruffner, B. W.; Regelson, W. (Virginia Cancer Cent., Richmond). *Ann. Surg.* 181(5):616-623, 1975.

A combined intraoperative and postoperative adjuvant program of 5-fluorouracil (5 FU) for patients undergoing "curative" resection for adenocarcinoma of the colon and rectum was undertaken. Beginning in January 1968, patients were randomly assigned to an intraluminal 5 FU or intraluminal control (saline) group and were so treated at the time of surgical resection if findings at that time indicated that all gross neoplastic disease could be resected. Patients with operative findings denoting incurability were eliminated from the study after surgical exploration. Patients receiving intralumina 5 FU (30 mg/kg) received i.v. 5 FU (10 mg/kg) on each of the first 2 postoperative days and 5 subsequent postoperative courses of p.o. 5 FU (90 mg/kg in each 18-day course) over a 1-yr period. After a time of 6 yr, 156 patients had entered the study. Survival curves and "disease-free" curves for comparison of the group receiving 5 FU and the control group reveal no significant benefit from this intensive adjuvant course of 5 FU thus far. It is concluded that the benefit of prolonged adjuvant therapy with 5 FU for patients undergoing "curative" surgery for colorectal cancer is inadequate to justify its general use at this time.

5937 THE LATEST FINDINGS IN THE DIFFERENTIAL RADIOLOGICAL DIAGNOSIS OF ACUTE ILEUS.

(Ger.) Bsteh, O. (Reg. Hosp., Mistelbach, Austria). *Radiol. Clin. Biol.* 44(1):14-23, 1975.

The pathophysiology of acute obstructive and paralytic ileus is considered, and the use of the barium enema to distinguish between these two conditions is discussed. In paralytic ileus, absorption, which ordinarily occurs in the right colon down to the splenic flexure, is replaced by exudation associated with gas production and motor paralysis. The left colon remains contracted, and the contrast medium passes readily into the right colon where it mixes with the formation of fluid levels. In obstructive ileus of the small intestine, the small intestine is distended with gas and shows fluid levels, while the colon is contracted throughout its entire length. Paralytic enterocolitis in elderly patients, which results from abnormal bacteriological flora in the small intestine, is characterized by discharge of toxic intestinal contents into the cecum where they produce inflammation and, in some cases, symptoms of appendicitis. In these patients, a barium enema provides a rapid and reliable diagnosis and often evacuates the intestine by dilating the spastically contracted left colon; cholinergic agents, administered parenterally, may also be indicated. A case report is presented for a patient in the 9th decade who developed acute ileus as a result of an extremely large scrotal hernia. A barium enema revealed paralytic ileus with enterocolitis, and the patient responded to conservative therapy. Barium enemas are also useful in the diagnosis of ileus in small children and of postoperative ileus. The technique is considered safe in all cases. In a 25-yr period, the author operated on 817 patients with perforated appendices with a total mortality of 4%; none of these patients died as a result of obstructive ileus. Cases of paralytic postoperative ileus were diagnosed and treated conservatively; none of these patients died either with the exception of 12 who also had peritonitis. Barium enemas are also recommended for establishing a differential diagnosis in rarer conditions, e.g., gallstone ileus, where the colon is empty and contracted, the small intestine is distended with fluid levels, and gas has collected in the biliary tract.

5938 BEHCET'S DISEASE AND TOXIC MEGACOLON.

(Ger.) Roenspies, U.; Saegesser, F. (Dept. Surg., Univ. Lausanne, Switzerland). *Schweiz. Med. Wochenschr.* 105(7):199-204, 1975.

A 31-yr-old woman with a history of sporadic arthralgias in the fingers, wrists, and spine, an allergy to dust, and hayfever was treated for bilateral uveitis and allergic conjunctivitis; no evidence of hypopyon was found at this time. Two months later she was hospitalized with a fever, erythema nodosum, aphthae of the oral and vaginal mucosa, dermatographia, colic-like abdominal pain, and postprandial diarrhea. *Staphylococcus aureus* was cultured from the stools. X-rays revealed dilatation of the ileum and the onset of irregularities in the wall of the colon. After 1 week she developed rectal bleeding, meteorism, and marked dilation of the colon with loss of haustration. These clinical and radiological signs of toxic megacolon were consistent with a diagnosis of ulcerative hemorrhagic proctocolitis. However, this diagnosis was ruled out by normal endoscopic and histological findings. The patient responded to conservative treatment with transfusions, protein and electrolyte substitution, antibiotics, corticosteroids, salicylazosulfapyridine, and vitamins but developed a pulmonary embolism after one week. Ten days after the development of toxic megacolon, x-rays showed "thumb printing" of the entire colon, as has been found in ischemic colitis; a double contrast enema showed colonic edema. A complete remission was obtained after 14 days of conservative therapy, but six months later a barium enema still revealed absence of haustration, particularly in the transverse and descending colon and the sigmoid, "thumb printing," and spicules. These findings are consistent with Crohn's disease or ischemic colitis. However, since the patient had no symptoms during the next 1.5 yr, Crohn's disease was ruled out. The history of bilateral uveitis, oral and vaginal aphthae, erythema nodosum, and pulmonary embolism suggests that the patient has Behcet's disease. Toxic magacolon is attributed to ischemic disorders in the entire colon associated with ulceration and a staphylococcal infection.

5939 CLINICAL ASPECTS, THERAPY, AND PROGNOSIS FOR CARCINOMA OF THE LARGE INTESTINE. *(Ger.)* Braun, L. (Surg. Clin. Polyclin., Univ. Munster, Germany). *Bruns Beitr. Klin. Chir.* 221(7): 503-515, 1974.

In a 22-yr period, 475 patients (266 males and 191 females, mean age 57.3 yr) were treated for histologically confirmed carcinomas of the colon, rectum, or anus. About half of all these tumors were located in the rectum, one-fourth to one-fifth in the sigmoid, and the rest occurred proportionately in the other parts of the large intestine. These patients consisted of 50% with stages A and B tumors, 17% with stage C, and 33% with stage D according to Duke's classification. Associated or pre-existing intestinal diseases consisted of hemorrhoids (15.6%), polyps (9.2%), typhoid fever (3.5%), diarrhea (3.1%), polyposis (2.9%), ulcerative colitis (2.6%), diverticulosis and/or diverticulitis (2.2%), fistulas and/or fissures (1.8%), periproctic abscess (0.7%), papilloma (0.4%), tuberculosis (0.4%), adenoma (0.2%), endometriosis (0.2%), and fibromatosis (0.2%). In the 390 cases for which information was available, 174 had metastases, 182 did not, and the presence or absence of metastases was in doubt in 34. The most common site of metastases was the lymph nodes (62 cases), followed by the peritoneum (43), liver (54), intestine (19), skin (16), lungs (10), female genitalia (9), bones (8), kidneys (4), and brain (2). Of these 457 patients, 423 (97.7%) were treated surgically. In 279 cases (66.0%) the tumor was completely removed; palliative surgery only was possible in 121 cases (28.6%); and tumors were inoperable at laparotomy in 23 cases (5.4%). Of the 457 operated patients, 102 (24.1%) died while still in the hospital; 12% died within the first 14 days after surgery. The causes of death were cardiovascular failure (31.4%), ileus (20.5%), inflammatory complications (19.6%), pulmonary embolism (16.7%), cachexia (8.0%), carditis (1.9%), and uremia (1.9%). Of the 16 patients treated conservatively, three lived for more than two yr. The five-yr survival rate was 0% for patients with inoperable tumors, 7.3% for those treated palliatively, and 32.6% for those who underwent radical surgery. The two-yr mortality was significantly lower (39.4%) in patients who received radiotherapy postoperatively than in those who did not (64.8%). After five yr, this difference was only 5.0%.

5940 A STUDY OF LYMPH NODES DRAINING COLORECTAL CANCER USING A TWO-STAGE INHIBITION OF LEUCOCYTE MIGRATION TECHNIQUE. *(E.)* Guillou, P. J.; Brennan, T. G.; Giles, G. R. (St. James Hosp., Leeds, England). *Gut* 16(4):290-297, 1975.

Leucocyte migration studies designed to investigate the sensitization of both peripheral and lymph node lymphocytes to tumor-associated antigens were performed in 14 patients suffering from adenocarcinoma of the colon and rectum. The results were compared with those of identical investigations on the peripheral blood and lymph node lymphocytes of ten control patients with benign gastrointestinal disease. Peripheral blood studies were performed on the morning of operation. Nodes were obtained from the root of the mesentery and from a paracolonic site in the controls and from the mesentery and a group of nodes draining the tumor in the patients; 14 nodes were obtained from the control subjects and 25 nodes from the patients with colorectal cancer. In five controls and 11 patients with cancer, a complete set of results was obtained for peripheral blood, mesenteric nodes, and paracolonic nodes. Leucocyte migration in the supernatant from control cells cultured with both normal colonic mucosal extract and tumor extract showed minor variations, but there were no significant differences between peripheral blood, mesenteric, and paracolonic lymph. The findings suggest that sensitization of local nodes may occur early in the progression of malignant disease; it may be lost when the lymph nodes become involved with tumor metastases. The results confirmed that some lymph nodes draining colorectal carcinomata contain sensitized lymphocytes, but the degree of sensitization to tumor extract does not seem greater than that seen in lymph nodes of the small bowel mesentery or of the peripheral blood.

LARGE INTESTINE

Ulcerative Colitis

6011 ULCERATIVE COLITIS AND ANAPHYLACTOID PURPURA.

(E.) Craig, R. M.; Ashman, M.; Feldman, S.; Hasegawa, J. (Northwest. Univ. Med. Sch., Chicago, Ill.). *Am. J. Dig. Dis.* 20(5):487-493, 1975.

A 21-yr-old male was hospitalized after an episode of bloody diarrhea and abdominal cramping. Two flat erythematous patches developed on his legs 6 months later which were termed "erythema marginatum." Recurrent erythematous eruptions occurred, occaisionally associated with diarrhea and abdominal cramping. Ulcerative colitis was diagnosed. His history included several strep throats throughout his life which had been treated with penicillin. One month prior to hospitalization, his own physician put him on 16 mg methylprednisolone/day which was tapered to 4 mg/day. A proctoscopic examination after admission revealed multiple circumscribed erythematous lesions seen throughout the rectal mucosa. A biopsy of the rectum revealed small foci of mucosal hemorrhages and some acute inflammatory cells in the tunica propria mucosae. A skin biopsy revealed leukoclastic angiitis. Prednisone was administered at 30 mg/day, gradually tapering. During the 2 yr following this hospitalization, he had had exacerbations of his skin lesions, sometimes associated with watery or bloody diarrhea, so that the dose of prednisone had to be adjusted. During one of these episodes the patient was treated for possible tuberculosis and a lung biopsy was consistent with Loeffler's pneumonitis. The patient is now maintained on prednisone as an outpatient. This is the first case of well-documented ulcerative colitis occurring during exacerbations of anaphylactoid purpura. It is suggested that other patients with anaphylactoid purpura be carefully observed for evidence of ulcerative colitis.

6012 PULMONARY VASCULITIS AND ULCERATIVE COLITIS.

(E.) Forrest, J. A. H.; Shearman, D. J. C. (R. Infirm., Edinburgh, Scotland). *Am. J. Dig. Dis.* 20(5):482-486, 1975.

A 37-yr-old man was admitted with a 6 week history of intermittent bloody diarrhea, tenesmus, malaise, anorexia, and a weight loss of 21 lb. Bilirubin was 2.0 mg/100 ml, SGPT 136 U/ml, alkaline phosphatase 120 King-Armstrong U/100 ml. The provisional diagnosis was ulcerative colitis and cholangitis. The patient became dyspneic at rest 2 days later and developed a cough with blood-stained sputum. His temperature rose to 39 C. Prednisolone (60 mg/day) abated the fever, and the dyspnea disappeared within 24 hr. His chest x-ray, which had shown a bilateral pulmonary shadowing, improved greatly. His liver tests remained abnormal. The SGPT and alkaline phosphatase did not improve with intermittent courses of antibiotics. Biopsies taken at colonoscopy showed ulcerative colitis. He was readmitted with mild diarrhea 1 1/2 yr later and a chest x-ray was normal. A few days later he became febrile with an unproductive cough and the chest x-ray showed bilateral pulmonary shadowing, which again resolved with prednisolone in 72 hr. At this time sigmoidoscopy showed a moderate proctitis. That the lung lesion responded promptly to corticosteroids, and that the lesion recurred, ruled out the diagnosis of subacute fibrosing alveolitis. In this patient, repeated cytomegalovirus titers were normal over a 2-yr period, and rectal and liver biopsies showed none of the pathologic lesions characteristically produced by that virus. Although fibrosing alveolitis has been reported in association with chronic active hepatitis, this patient's liver pathology is one of a pericholangitis secondary to ulcerative colitis. Although a lung biopsy was not performed, the most likely explanation for the patient's lung lesion is that he suffered two episodes of pulmonary vasculitis which on each occasion coincided with a relapse of his ulcerative colitis. It is suggested that there should be greater awareness that ulcerative colitis patients may develop pulmonary disease, either associated with their colitis *per se*, or secondary to salazopyrine.

6013 ESTIMATION OF CARCINOEMBRYONIC ANTIGEN IN ULCERATIVE COLITIS WITH SPECIAL REFERENCE TO MALIGNANT CHANGE.

(E.) Dilawari, J. B.; Lennard-Jones, J. E.; Mackay, A. M.; Ritchie, J. K.; Sturzaker, H. G. (St. Mark's Hosp., London, England). *Gut* 16(4):255-260, 1975.

Carcinoembryonic antigen (CEA) levels in patients with colitis were investigated and the findings correlated with various clinical aspects of the disease. In particular, the question as to whether CEA levels could be correlated with the presence of carcinoma or of dysplastic epithelial changes without carcinoma was studied. A hospital control group was composed of 59 patients with the following diagnoses: idiopathic megacolon or Hirschsprung's disease (7), diverticular disease without inflammation (5), rectal prolapse (5), hemorrhoids (18), anal fissure (6), perianal hematoma (3), other anal conditions (4), and miscellaneous conditions (11). A second patient group consisted of 139 patients with uncomplicated ulcerative colitis, i.e., without evidence of dysplastic change in the rectal mucosa or carcinoma. A third patient group consisted of 7 patients with ulcerative colitis and epithelial dysplasia. The last patient group contained 7 individuals (6 men and 1 woman, aged 24-63 yr) with established carcinoma in ulcerative colitis. In a group of 70 healthy controls, all individuals had CEA levels of less than 17.5 ng/ml. These results are different from those in the hospital control group where 8 of the 59 patients had values higher than 17.5 ng/ml with a range of from 1 to 36 ng/ml. Generally, there was little difference in the results for patients with colitis and those in the hospital control group. In the colitic patients no correlation could be established between the actual CEA levels and the age of the patient, the activity of the disease, or the extent of involvement. Only 1 patient among the 7 with dysplastic changes in the rectal mucosa had a CEA level above the values found in the hospital control group. One patient among the 7 with malignant change had a CEA level of 105 ng/ml; the other 6 patients, including one with recurrent growth and peritoneal metastases, all had CEA values within the range of the hospital control group. Thus, the results of this study show that CEA values in ulcerative colitis have no correlation with length of history, extent of disease, or degree of activity. It is unlikely that malignant change would be detected by this test earlier than by other methods of investigation. It is not recommended that routine CEA examinations be performed on patients with ulcerative colitis.

6014 CARCINOEMBRYONIC ANTIGEN IN PATIENTS SUFFERING FROM ULCERATIVE PROCTOCOLITIS.

(E.) Mitchell, A. B. S.; Gill, A. M.; Orchard, R. T.; Parkins, R. A. (Prince of Wales's Hosp., London, England). *Am. J. Dig. Dis.* 20(5):407-417, 1975.

Carcinoembryonic antigen (CEA) was measured by radioimmunoassay in blood samples obtained from all 59 patients with ulcerative proctocolitis seen within a 4-month period. The characteristics of this group of patients were compared with reported epidemiological studies in this disease. The current patients had a similar sex ratio and age of onset as those in other studies, but the extent of their disease was more limited. Among these 59 patients, 11 had elevated circulating CEA values. One of the 11 had a colonic carcinoma and another was pregnant. Excluding these two patients, the overall prevalence of elevated CEA levels was 17.5%. The prevalence in ulcerative proctitis was 7.1%, and in colitis was 19.9%. The patients with elevated plasma CEA values were compared with remaining patients in relation to factors known to be associated with an increased propensity for the development of colorectal carcinoma complicating ulcerative colitis. There was no difference in mean age of the patients at disease onset, nor was there any difference in disease duration, extent, and control. A significant correlation was found, however, between elevated plasma CEA levels and the severity of the initial attack. Accordingly, a significantly greater proportion of those with normal CEA concentrations, as compared with those with elevated CEA concentrations, had suffered a mild onset of ulcerative proctocolitis. One patient with premalignant changes in the rectal mucosa had consistently normal concentrations of plasma CEA. There was no significant correlation between elevated plasma CEA values and disease activity. The mean age of the 2 groups of patients was similar. During follow-up periods of at least 18 months no carcinoma has manifested in any patient. The significance of the elevated levels of circulating CEA in patients who suffer from ulcerative proctocolitis and do not have evidence of carcinoma cannot be decided at present. The raised CEA levels can only be regarded as genuine false positives in the detection of colorectal carcinoma should this complication eventually be found with the same frequency among those with normal and those with elevated circulating CEA levels.

6015 CARCINOMA AND EPITHELIAL DYSPLASIA COMPLICATING ULCERATIVE COLITIS.

(E.) Cook, M. G.; Goligher, J. C. (Gen. Infirm. Leeds, England). *Gastroenterology* 68(5):1127-1136, 1975.

The pathology of 19 specimens of carcinoma complicating ulcerative colitis was reviewed with particular attention given to the incidence of epithelial dysplasia. The 19 patients (aged 28-74 yr) had a history of colitis ranging from 3-34 yr in duration. The carcinomas were more frequently multiple, more evenly distributed in the large intestine, and much more often of atypical macroscopic appearances and of mucoid histological type than ordinary colorectal carcinomas, but the proportion of poorly differentiated tumors complicating ulcerative colitis was not as high as had been previously reported. Of these 19 patients, 26% are alive and well at least 5 yr after surgery. Unequivocal epithelial dysplasia was demonstrated in some part of the large intestine in 15 of 19 specimens with colitis carcinoma, but was also found in 4 of 14 specimens from a "control" series of patients with longstanding total colitis but without carcinoma. Therefore, the finding of dysplasia in a rectal biopsy of a patient with colitis is not a reliable guide to the presence of a frank carcinoma elsewhere in the intestine. Whether such a finding may indicate a predisposition to the development of a growth in the future cannot be determined from the data of this study. When present in colitis, epithelial dysplasia is often patchy in distribution and frequently spares the rectum even in patients with definite carcinomas; this makes a negative rectal biopsy particularly unreliable in deciding on the absence of a tumor or the lack of predisposition to its development. It is suggested that multiple biopsies from different parts of the colon as well as the rectum are desirable if mucosal sampling is to be employed as a screening test.

6016 MONOAMINE OXIDASE ACTIVITY IN PATHOLOGICALLY CHANGED TISSUE OF THE LARGE INTESTINE.

PANCREAS

6024 ELECTROPHORETIC PATTERNS OF ALKALINE PHOSPHATASE ISOENZYMES IN HUMAN SERA WITH ABNORMALLY HIGH ACTIVITY, AND AN UNUSUAL BAND OBSERVED IN SERA OF PATIENTS WITH PANCREATIC CANCER. *(E.)* Cha, C. J. M.; Mastrofrancesco, B.; Cha, S.; Randall, H. T. (Rhode Island Hosp., Providence). *Clin. Chem.* 21(8):1067-1071, 1975.

The separation by electrophoresis of the isoenzymes of alkaline phosphatase on cellulose acetate membranes and an unusual alkaline phosphatase band observed in sera from patients with pancreatic cancer is reported. Alkaline phosphatase isoenzymes in sera were resolved into seven different bands: L_1, B_1, Pl, L_2, I_1, I_2 and Pa, in decreasing order of electrophoretic mobility. The slowest moving band (Pa) was observed in the sera of 16 patients, 15 with pancreatic cancer and one with hemochromatosis. Sera of 50 other patients with malignant or benign diseases did not show the Pa band. The Pa band was more heat labile than the liver isoenzyme (L_1). The behavior of the Pa band toward inhibitors (L-phenylalanine and L-homoarginine) was similar to that of L_1. Sera containing the Pa band exhibited a diffuse band in the region where isoenzymes of intestinal origin migrate; however, its heat stability and stereospecific inhibition were different from those of intestinal isoenzymes in sera showing no Pa band. It is suggested that further studies be carried out to determine whether the 'slow-moving' bands observed by different studies are identical, and to establish the diagnostic value and the cellular origin of the serum Pa band.

6025 ASSOCIATION OF POLYARTHRITIS, SUBCUTANEOUS NODULES, AND PANCREATIC DISEASE. *(E.)* Tannenbaum, H.; Anderson, L. G.; Schur, P. H. (Robert B. Brigham Hosp., Boston, Mass.). *J. Rheumatol.* 2(1):14-20, 1975.

A patient with polyarthritis, panniculitis, and pancreatic carcinoma was given metabolic and immunologic tests to find a relation between the joint, skin and pancreatic lesions. A 63-yr-old white male presented with migratory polyarthritis of 2 months duration. Tender skin nodules developed over the right tibia and both malleolar areas of the right ankle 2 weeks prior to admission. These nodules were indurated, warm, and erythematous. There was a history of granulomatous prostatitis and diabetes mellitus. Aspiration of the arthritic left knee yielded a clear serous fluid, but a second aspiration after 6 days yielded a thick creamy synovial fluid containing fat globules. Needle aspiration from the fluctuant subcutaneous tissue of a nodular lesion yielded a brown viscous fluid containing similar fat globules. Both this and the synovial fluid contained small, negatively birefringent, rectangular particles between the fat globules. Skin biopsy revealed a marked neutrophilic infiltrate involving subcutaneous tissue and deep dermis, with extensive focal liquifaction-type necrosis, focal chronic inflammation, scattered foam cells, and fibrinoid necrosis of small vessel walls. Liver biopsy revealed a metastatic undifferentiated tumor. The left knee effusion reaccumulated within 2 days, and new areas of synovitis and panniculitis appeared. Prednisone (60 mg/day) controlled the arthritis but not the panniculitis. Chemotherapy with bleomycin, adriamycin, cyclophosphamide, oncovin, and prednisone for the tumor also resolved the panniculitis but the patient died shortly after. Autopsy revealed a well-differentiated acinar cell carcinoma in the tail of the pancreas. Lungs showed interstitial thickening with fibrosis and edema. The serum contained elevated lipase levels of 11.9-12.3 Cherry-Crandall U. The creamy joint fluid had a fatty acid of 26mg%, glycerol 41 mg%, and triglyceride 48mg%; there were 2122 M lactate/liter. Skin biopsy from a panniculitis area showed no immunoglobulins or complement. Lymphocytes failed to take up ^{3}H-thymidine when exposed to non-specific mitogens, tuberculin, or streptokinase/streptodornase, but did respond to *Candida albicans*. Blood immunoglobulins, gamma G subclasses, hemolytic complement, and complement components were normal. Radioimmunoassay for the carcinoembryonic antigen was positive (18.5 ng/ml). It is concluded that lipolysis and immunologic mechansims are not involved in the pathogenesis of this disease.

6026 IMMUNOGLOBULIN CHARACTERIZATION OF HUMAN PANCREATIC FLUID. *(E.)* Brasher, G. W.; Dyck, W. P.; Hall, F. F.; Spiekerman, A. M. (Scott White Clin., Temple, Texas). *Am. J. Dig. Dis.* 20(5): 454-459, 1975.

The concentration and stability of pure pancreatic fluid immunoglobulins were studied in two patients with traumatic pancreatic fistulae. Single radial diffusion demonstrated that the fluid of both patients contained detectable levels of IgG and IgA. IgD and IgM were found in 1/3 of the random samples in concentrations of 2.0-2.5 mg/100 ml, and 5-7 mg/100 ml, resp. One random specimen contained 216 U/ml IgE. One patient had 15 mg/100 ml IgG, 3.6 mg/ml IgA, 2.8 mg/100 ml IgM, and less than 0.9 mg/100 ml IgD. The IgG:IgA ratio ranged from 0.65-4.70. IgA molecular weight was estimated at 155,000 daltons by gel-filtration column chromatography. There was a progressive decay of all immunoglobulin fractions during storage at 4 C. By 10 days, no immunoprecipitates could be detected, while proteolytic activity had progressively increased. It is concluded that the five major immunoglobulins are present in human pancreatic fluid.

6027 EVALUATION OF BILIARY AND PANCREATIC FUNCTION IN PANCREOLITHIASIS: VALUE OF THE DETERMINATION OF γ-GLUTAMYL TRANSPEPTIDASE. *(E.)* Nakajima, S.; Noda, A.; Toda, Y. (Nagoya Hoden Eisei Univ. Sch. Med., Japan). *Arch. Intern. Med.* 135(6):829-831, 1975.

The pancreozymin-secretin test was used to determine γ-glutamyl transpeptidase, bile pigment, amylase concentrations and volume of duodenal aspirate. Patients with pancreolithiasis (10) and 10 controls had a triple lumen tube with two balloons, positioned fluoroscopically in the third portion of the duodenum after an overnight fast. A skin test with pancreozymin was performed at the beginning of each test. A quantitative duodenal aspirate was obtained for two 10 min control periods after the aspirate became alkaline. Then, 1 CHR U/kg pancreozymin was injected i.v. and three additional samples of aspirate were collected at 10 min intervals. Secretin (1 CHR U/kg) was then injected i.v., and six more 10 min samples were collected. Blood specimens were taken immediately before the hormone injections, and 30 and 60 min after the secretin. Routine liver function tests and drip infusion cholangiography in all patients showed normal results. The concentrations and outputs of γ-glutamyl transpeptidase in response to the two hormones were significantly greater in the patients than in the controls. There was no correlation between the enzyme and the bile pigment concentrations. Mean amylase outputs in pancreolithiasis patients were significantly less than those of controls, but secretion was not impaired in the form of the disease with bulky calculi in the head of the pancreas. Pancreozymin-secretin stimulation produced no increase above the normal levels of 40 mU/ml for serum γ-glutamyl transpeptidase and 200 U/100 ml for amylase, in the controls. In the patients, the provocative serum enzyme test was positive (rising to at least twice the initial values) in 3 for transpeptidase and in 1 for amylase. It is concluded that γ-glutamyl transpeptidase in posthormonal aspirates is significantly greater in patients than in controls.

6028 PANCREATIC CHOLERA (W.D.H.A. SYNDROME): HISTOCHEMICAL AND ULTRASTRUCTURAL STUDIES. *(E.)* Rambaud, J. C.; Galian, A.; Scotto, J.; Hautefeuille, P.; Matuchansky, C.; Modigliani, R.; Pessayre, D.; Bernier, J. J. (Hosp. St.-Lazare, Paris, France). *Virchows Arch.* [*Pathol. Anat.*] 367(1):35-45, 1975.

A detailed histochemical and ultrastructural study was made of a pancreatic tumor in a case of pancreatic cholera. A 38-yr-old woman presented with acute dehydration and anuria. There was a 7-yr history of recurrent diarrhea and a 2-yr history of five progressive quadriplegic attacks. Laboratory findings showed hypokalemia (1.8 mEq/liter), high fecal water and potassium losses (3270 ml/day and 160 mEq/liter/day, resp.), and basal gastric achlorhydria. Laparotomy showed a tumor of the body of the pancreas with multiple small metastases on the liver, peritoneum, and ovaries. The tumor was resected, and radioimmunoassay and bioassay showed large amounts of vasoactive intestinal peptide and a small amount of glucagon. The primary tumor, but not the metastases, contained large cysts lined in some places by small intestine-like epithelium and in other areas by cells similar to pancreatic duct cells. These exocrine-like structures were closely connected with endocrine cells, suggesting a mixed tumor. Apart from a few D cells, the endocrine tumor cells could not be identified by histochemical stains. Ultrastructurally the cells resembled gastric and duodenal D1 cells in that they contained small secretory granules (diameter less than 300 nm) and numerous cytoplasmic bundles of filaments. No intermediate cells containing both zymogen and endocrine-like granules were found in the tumor. Lymph node, liver, and peritoneal metastases were composed exclusively of endocrine cells. Normal duodenal D1 cells have been reported to produce gastric inhibitory peptide, a substance structurally and biologically similar to the vasoactive intestinal peptide secreted by the tumor. Histological patterns were normal in the gastric, gallbladder, jejunal, ileal, and right and left colonic mucosa. This strongly suggests that a humoral agent (possibly vasoactive intestinal peptide) secreted by the pancreatic tumor is responsible for impaired intestinal function and abnormalities in gastric juice and gallbladder bile composition in pancreatic cholera.

6029 PANCREATIC SECRETION IN PERNICIOUS ANEMIA. *(E.)* Dreiling, D. A.; Greenstein, A. J. (Mt. Sinai Sch. Med., New York, N.Y.). *Am. J. Gastroenterol.* 63(6):495-497, 1975.

This report presents data from standard secretin tests performed on 257 control subjects, 19 patients with pernicious anemia, 67 patients with atrophic gastritis with achlorhydria, and 11 patients with Zollinger-Ellison syndrome. Gross inspection of the data from pernicious anemia patients indicates that 7 of the 19 secreted water and bicarbonate in the hypersecretory range. The increased secretion in pernicious anemia patients is consistent for flow, bicarbonate output, and amylase production. Patients with atrophic gastritis showed average responses similar to those with pernicious anemia. However, the increases in secretion in pernicious anemia and atrophic gastritis were not of the order of magnitude of those seen in Zollinger-Ellison syndrome and were not statistically significant. Preliminary observations on serum gastrin levels and their response to secretin indicated that levels are very high in pernicious anemia and atrophic gastritis. However, the gastrin is "Big Big" gastrin in contrast to the lower molecular gastrins found in Zollinger-Ellison syndrome. Moreover, the gastrin level in pernicious anemia and atrophic gastritis does not respond excessively to secretin as observed in the Zollinger-Ellison syndrome. These data suggest that the pancreatic parenchyma in pernicious anemia and atrophic gastritis may be responding to the hypergastrinemia of these conditions but at a minimal level consistent with the relatively inactive form in which the gastrin, "Big Big" gastrin, is secreted into the blood. Alternatively, the increased flow, bicarbonate output, and enzymes secretion may result from the synergism between the increased but relatively inactive serum gastrin and the endogenous secretin stimulus.

6030 VASCULARIZATION OF THE PANCREAS AFTER GASTRIC SURGERY. *(Ger.)* Barke, R.; Schulz, H. G. (Dep. Med., Karl Marx Univ., Leipzig, Germany). *Radiol. Diagn. (Berl.)* 15(1):13-20, 1974.

To study the effect of gastrectomy on vascularization of the pancreas, combined selective angiography of the celiac and mesenteric arteries was performed on four patients 2 to 6 yr after they had undergone Billroth II procedures for peptic ulcer. Three of these patients had undergone total orad antecolic resections with ligation of the right gastroepiploic artery close to the duodenum; in some cases the gastroduodenal or pancreaticoduodenal arteries were included. The left gastroepiploic artery was also ligated, so that only the left gastric artery supplied the gastric stump. Selective celiac angiography showed postoperative hypoplasia of the gastroduodenal artery in a 46-yr-old man who had undergone surgery 3 yr before for an ulcer of the anterior wall of the duodenum; the superior posterior and superior anterior pancreaticoduodenal arteries and the right gastroepiploic artery were not visualized. The transverse pancreatic artery was very small and the left gastric artery was relatively small. Combined selective celiac and superior mesenteric angiography in a 45-yr-old man, who had undergone gastrectomy 2 yr before for a recurrent duodenal ulcer, revealed a normal pancreaticoduodenal arcade due to careful ligation of the right gastroepiploic artery. In a 47-yr-old man who had undergone surgery 6 yr before for an ulcer of the anterior wall of the duodenum, combined angiography demonstrated some hypoplasia of the gastroduodenal artery; upper jejunal branches were drawn up from the superior mesenteric artery. Some branches of the pancreatic artery to the posterior body of the pancreas were also detected. The pancreaticoduodenal arcades were normal in a 35-yr-old man who had undergone a Billroth II gastroenterostomy with a retrocolic anastomosis 5 yr before, surgery for a gastrojejunocolonic fistula 2 yr before, conversion of the retrocolic into an antecolic anastomosis, repeated gastrectomy for an anastomotic ulcer 1 yr before, and resection for a perforated jejunal ulcer 6 months before. A large pancreatic artery, from which the transverse pancreatic artery originated, provided a very good blood supply to the head of the pancreas. The right hepatic artery originated from the proximal trunk of the superior mesenteric artery. In this case, a variation in the course of the right gastroepiploic artery apparently made a good pancreatic blood supply possible. It is concluded that disorders in pancreatic function in gastrectomized patients may be attributed to a decreased pancreatic blood flow.

PANCREAS

Pancreatitis

6045 HEREDITARY PANCREATITIS. NONSPECIFICITY OF AMINOACIDURIA AND DIAGNOSIS OF OCCULT DISEASE. *(E.)* Riccardi, V. M.; Shih, V. E.; Holmes, L. B.; Nardi, G. L. (Massachusetts Gen. Hosp., Boston). *Arch. Intern. Med.* 135(6):822-825, 1975.

A family with hereditary pancreatitis involving males in five generations and the initial proband (originally diagnosed at 11 months) is reported in order to emphasize the marked phenotypic variation found in this disease, the ability to make a diagnosis in an asymptomatic individual, and the nonspecific nature of any associated aminoaciduria. Hereditary pancreatitis was diagnosed in four cases, twice based on clinical and surgical findings, once on back pain and pancreatic calcifications, and once by laboratory and x-ray film studies. Suspected hereditary pancreatitis was diagnosed four times, once from old medical records, and in three cases from descriptions provided by family members. The autosomal dominant nature of the disease in this family was evident from multiple generation involvement and the male-to-male transmission. The morphine prostigmine test and the hypotonic duodenogram were helpful in establishing the diagnosis. On the basis of 24-hr urinary amino acid excretion rates available from other cases, and from those in this family who were available, it is concluded that the aminoaciduria previously associated with this disorder is coincidental or nonspecifically related to acute pancreatic inflammation. An increased risk for pancreatic carcinoma was emphasized by the concern for that complication in the proband's grandfather. However, counseling regarding the risk for developing pancreatic carcinoma in hereditary pancreatitis in clearly affected and especially asymptomatic individuals at risk cannot be done until more information is available.

6046 CLINICAL TRIAL OF CDP-CHOLINE AS A MEDICAMENT FOR ACUTE PANCREATITIS AND ITS RELATION TO PANCREAS AND LIVER DAMAGE IN ACUTE PANCREATITIS. *(E.)* Ozawa, K.; Kitamura, O.; Uchida, K.; Honjo, I. (Fac. Med., Kyoto Univ., Japan). *Bull. Soc. Int. Chir.* 33(5/6):483-489, 1974.

In an attempt to understand some of the basic mechanisms involved in the induced ischemic state, changes of oxidative phosphorylation of the pancreas in acute pancreatitis were studied. Pancreas and liver mitochondria from guinea pigs were prepared; oxygen consumption was measured polarigraphically and phosphorylative efficiency was measured simultaneously with oxygen utilization by following pH changes with a glass electrode. Spectrophotometric techniques were used to assay respiratory enzymes. The maximal phosphorylation rate in brain and pancreas mitochondria declined rapidly, as compared to liver, kidney and heart mitochondria, where the initial rate of phosphorylation remained almost constant for 10 min. In pancreas mitochondria, state 3 respiration (with glutamate as the substrate) declined rapidly, whereas that with succinate plus glutamate was slightly affected, leading to a rapid decrease in the glutamate to succinate ratio to less than 1/3 of the original value 5 min after ischemia. The decrease in the glutamate to succinate ratio paralleled the fall in the lipid acyl ester bonds and a concomitant rise in lysolecithin. Administration of 15 mg/kg CDP-choline to 53 patients with pancreatitis showed a 60% amelioration of symptoms. It is concluded that CDP-choline prevents mitochondrial derangement due to aging-induced activation of phospholipase A.

6047 USE OF A PERITONEAL LAVAGE IN THE DIAGNOSIS OF EXPERIMENTAL ACUTE PANCREATITIS. *(E.)* Machiedo, G. W.; Brown, C. S.; Lavigne, J. E.; Rush, Jr., B. F. (Martland Hosp., New Jersey Med. Sch., Newark). *Surg. Gynecol. Obstet.* 140(6):889-892, 1975.

Additional biochemical parameters for the recognition of acute pancreatitis are presented, and how they can aid in the diagnosis of the disease is discussed. Dogs (24) were divided into five groups. Under sodium pentothal anesthesia, those in the control group underwent no further manipulation; another group underwent laparotomy only; and dogs in the last three groups had induced pancreatitis (injection of bile into the pancreas), intestinal ischemia and duodenal perforation, resp. Analysis was made of serum and peritoneal lavage fluid in a dog from each group at 30-min intervals for 4.5 hr. Parameters which were significantly elevated in dogs with pancreatitis compared with other groups included fluid amylase, LDH, proteolytic activity and intestinal alkaline phosphatase and serum amylase. It is concluded that these biochemical differences in the lavage fluid, when considered together with the physical characteristics of the fluid, can significantly aid the clinician in arriving at the diagnosis of acute pancreatitis.

6048 PANCREATIC FUNCTION TEST IN PATIENTS WITH BILLROTH II RESECTION WITH THE AID OF AN ENDOSCOPE. *(E.)* Tympner, F.; Rosch, W. (Dep. Med., Univ. Erlangen-Nuremberg, Erlangen, Germany). *Endoscopy* 6(4):245-257, 1974.

A new method is presented which allows a quantitative pancreatic function test in patients with Billroth II resection. A Lagerlof tube and an endoscope with prograde optics was introduced without premedication and the tube was placed into the afferent loop under visual control. The procedure was successfully applied in 12 patients in whom retrograde pancreatography was also attempted. Comparison of pancreatograms and pancreatic secretion after secretin-pancreozymin stimulation showed that the function test is superior to radiology. While retrograde pancreatography produced successful results in only seven of the patients, a clinical diagnosis was obtained in all cases with the use of the pancreatic function test. Although there is a certain amount of annoyance to the patient without premedication, it is concluded that this test allows the clinician to gather valuable information in patients likely to have chronic pancreatitis, and in whom other procedures such as retrograde pancreatography are unsuccessful.

6049 A PATHOGENESIS FOR ALCOHOLIC PANCREATITIS. *(E.)* Cameron, J. L.; Zuidema, G. D.; Margolis, S. (Johns Hopkins Med. Inst., Baltimore, Md.). *Surgery* 77(6):754-763, 1975.

To determine whether increased serum triglyceride levels secondary to alcohol ingestion might play an important intermediary role in the initiation of pancreatitis, patients with prior episodes of alcoholic pancreatitis associated with hypertriglyceridemia were admitted to a metabolic ward and studied. Hypertriglyceridemia was induced by dietary means, in the absence of alcohol, in an attempt to reproduce the symptoms of pancreatitis. During a quiescent period in their diseases, 12 patients with prior alcoholic pancreatitis were studied. By lipid feeding (316-894 g/day), significant hypertriglyceridemia (greater than 600 mg/100 ml) was induced in 11 of the 12. Seven of these developed abdominal pain similar to but not as severe as that experienced during prior attacks of pancreatitis. Of these seven, four developed serum amylase elevation, and of the remaining three, one had a serum lipase elevation and one a urinary amylase elevation. It is suggested, on the basis of these and previous data, that increased serum triglycerides act as important intermediaries in the pathogenesis of acute pancreatitis in some alcoholic patients.

6050 LACTOFERRIN IN THE DUODENAL JUICE OF PATIENTS WITH CHRONIC CALCIFYING PANCREATITIS. *(E.)* Estevenon, J. P.; Sarles, H.; Figarella, C. (Dig. Pathol. Res. Unit., INSERM, Marseilles, France). *Scand. J. Gastroenterol.* 10(3):327-330, 1975.

Since lactoferrin is present in the pancreatic juice of patients with chronic calcifying pancreatitis, but has not been found in normal juice, its presence in pathological pancreatic juice was investigated for possible clinical significance. A technique for collecting human duodenal juice with a rubber tube and preventing its contamination with saliva is described. The presence of lactoferrin was investigated in the duodenal juice of 15 patients with chronic calcifying pancreatitis, 52 controls without evidence of pancreatic disease and nine cases of pancreatic disease other than chronic calcifying pancreatitis. Immunological methods were used to determine the presence of lactoferrin before and after an i.v. injection of cholecystokinin-pancreozymin (3 Crick-Harper-Raper U) plus secretin (1 CU). Tests for lactoferrin were positive in 11, negative in three, and inconclusive in one patient(s) with chronic calcifying pancreatitis. All nine patients with pancreatic disease other than chronic calcifying pancreatitis were negative for lactoferrin. Of the 52 controls, five were positive, six inconclusive, and 41 negative for lactoferrin. It is suggested that this test be used in the diagnosis of chronic calcifying pancreatitis.

6051 MAGNESIUM AND CALCIUM IN DUODENAL JUICE: SECRETION PATTERN IN CHRONIC PANCREATITIS AND IN PRIMARY HYPERPARATHYROIDISM. *(Ger.)* Baltzer, G.; Goebell, H.; Muller-Reinhardt, B. (Med. Clin., Phillipps Univ., Marburg/Lahn, Germany). *Klin. Wochenschr.* 52(2):74-79, 1974.

The secretion of magnesium (concentration and output) was measured in human duodenal juice before and after stimulation of the pancreas by secretin and pancreozymin (1 unit/kg) and compared with data for calcium. Subjects included 27 (12 women, 15 men, average age 49.9 yr) with normal pancreatic function; 23 patients (8 women, 15 men, average age 38.7 yr) with moderate and 22 patients (8 women, 14 men, average age 45.9 yr) with severe pancreatic insufficiency; and 14 (7 women, 7 men, average age 41.5 yr) with primary hyperparathyroidism. In all functional states of the normal pancreatic gland, magnesium and calcium were secreted in close positive correlation. The concentration was lowered after secretin. Pancreozymin increased both the concentration and the output of the two elements. The parallel secretion was also found, with few exceptions, in patients with pancreatic insufficiency. The secretion of both electrolytes was significantly reduced after pancreozymin with the lowered enzyme secretion. In primary hyperparathyroidism associated with normal pancreatic function a higher than normal concentration and output of magnesium and calcium after pancreozymin were measured. When enzyme secretion in these patients was disturbed, the secretion of the two electrolytes was reduced. In primary hyperparathyroidism the secretion of magnesium was more strongly stimulated by pancreozymin than that of calcium. The behavior of magnesium and calcium was no longer parallel in this case. Observations made in the analysis of enzyme fractions in five different phases of enzyme secretion in different phases of pancreatic stimulation suggest the possibility that the deviating behavior of magnesium is related to a preferred secretion of an enzyme protein.

6052 ALCOHOLIC HYALIN-LIKE BODIES FOUND IN THE PANCREATIC ACINAR CELLS AND NERVE CELLS OF THE BRAIN. *(E.)* Kojima, K. (Cent. Pathol., Kooseiren, Niigata, Japan). *Acta Pathol. Jpn.* 25(3):281-293, 1975.

The presence of alcoholic hyalin in pancreatic acinar cells and nerve cells of the caudate nucleus of the brain is reported. In a series of about 150 autopsy cases of alcoholics, hyalinoid body formation in acinar cells was demonstrated in 13. Of these 13, 2 also had hyalinoid bodies in the nerve cells of the caudate nucleus. Electron microscopy performed on the pancreatic tissue of 2 of the cases showed these bodies to have a fibrillar filamentous structure consisting of fine filaments in parallel alignment, and no limiting membrane. Each fibril was 65-379 Å in diameter. The hyalinoid bodies in the brain cells had the same fibrillar filamentous structure, with fibrils ranging from 53-155 Å in diameter. Some of the filaments showed periodicity of alternately arranged electron-dense particles of 130 Å and electron-lucent spaces of 50 Å. It is concluded that hyalinoid bodies found in pancreatic acinar cells and brain nerve cells of alcoholics greatly resemble the alcoholic hyalin in liver cells.

6053 IMMUNOLOGICAL PARTICIPATION IN CHRONIC CALCIFYING PANCREATITIS. *(E.)* Dani, R.; Antunes, L. J.; Ribeiro, J. E. F.; Nogueira, C. E. D.; Ribeiro, T. (Dep. Intern. Med., Fed. Univ. Minas Gerais, Belo Horizonte, Brazil). *Digestion* 11(5/6): 333-337, 1974.

Immunologic participation in chronic pancreatitis was studied in 12 patients with chronic calcifying pancreatitis and 20 healthy volunteers. Among the pancreatitis patients, 9 were alcoholic, 11 were diabetic, and 5 had steatorrhea; none was receiving steroids. Serum samples were studied by immunodiffusion, indirect immunofluorescence, and an anticomplementary technique; the percentage of peripheral blood lymphocytes was also determined. Compared with the controls, the mean serum concentrations of IgA and IgM were significantly elevated in the patients with chronic pancreatitis. One patient had autoantibodies against nuclear factors, smooth muscle, and IgG, 2 patients had autoantibodies to gastric parietal cells, and immune complexes were observed in 11 patients and none of the controls. The percentages of T-active and total T lymphocytes were significantly decreased in the pancreatitis patients, while the B lymphocyte levels were normal. These results suggest an immunologic participation in chronic calcifying pancreatitis, which might explain the persistence and progressive nature of the disease.

6054 AN ALTERNATE MECHANISM FOR THE FORMATION OF PROTEIN PLUGS IN CHRONIC CALCIFYING PANCREATITIS. *(E.)* Allan, J.; White, T. T. (Univ. Washington Sch. Med., Seattle). *Digestion* 11(5/6): 428-431, 1974.

To study the mechanism of protein plug formation in chronic calcific pancreatitis, protein precipitation in the ductal pancreatic juice was studied in specimens obtained after surgery on patients with varying types of pancreatic disease. Two general types of precipitation phenomena were observed. Concentration-dependent precipitation occurred when specimens of inactive pancreatic juice secreted at concentrations greater than 3 mg/ml were chilled on ice or stored at 4 C. The fine precipitates thus formed could be redissolved by warming at 37 C. With specimens containing active chymotrypsin, insoluble flocculent precipitates were formed even from dilute solutions; these precipitates did not redissolve on warming. Based on these results, it is suggested that the etiology of plug formation and calcification in the small and large ducts of patients with chronic calcifying pancreatitis is due to a series of partial activations of zymogens in the ductules; this process, which proceeds by an unknown mechanism, results in precipitate formation in localized regions of the pancreas with later spreading throughout the gland. The precipitates not washed out by the newly-secreted juice would enlarge and calcify *via* the absorption of proteins and salts from the pancreatic juice.

6055 SERUM ANTIBODIES IN HUMAN PANCREATIC DISEASE.

(E.) Lendrum, R.; Walker, G. (St. Mary's Hosp., London, England). *Gut* 16(5):365-371, 1975.

The presence of serum antibodies in human pancreatic disease was studied using immunofluorescent techniques. Serum samples from 61 patients with acute pancreatitis, 12 patients with relapsing acute pancreatitis, 14 patients with chronic pancreatic disease, 13 patients with pancreatic neoplasms, and 12 healthy adults were studied by indirect immunofluorescence using human pancreas as substrate; the positive sera were then retested after absorption with human RBC or human saliva. The positive sera were also tested against human pancreatic subfractions, human thyroid and stomach, rat liver and kidney, and rat and guinea pig pancreas. A reproducible pattern of immunofluorescence, consisting of a coarse granular appearance in the cytoplasm of the acinar cells, was obtained with the sera of 21 patients with acute pancreatitis, 3 of 381 patients without evidence of pancreatic disease, and 1 healthy adult. Absorption of the positive sera with A, B, or O blood cells or with saliva of the 3 Lewis phenotypes had no effect on the immunofluorescence reactions. The immunoglobulin classes of the antibodies in the positive sera were IgG in 1 patient, IgA in 7 patients, IgG and IgA in 13 patients, IgM in 1 control, and IgG in the other 3 controls. Complement fixation was demonstrated in only 1 of 15 positive sera. The positive sera gave no consistent or characteristic pattern when tested against human thyroid and stomach, and against rat liver and kidney; the results of the tests for species specificity were inconclusive. Tissue fractionation and absorption studies indicated that the antigen involved was located in the microsomal pancreatic fraction and that it may have been organ specific. The precise nature of the antigen is unclear, although it is unlikely that it is an enzyme.

6056 PANCREATITIS FOLLOWING INTESTINAL BYPASS FOR OBESITY.

(E.) Sorrell, V. F.; Knight, D. H.; Burcher, S. K. (Middlemore Hosp., Auckland, Australia). *Aust. N. Z. J. Surg.* 45(2):163-167, 1975.

Of 24 patients operated on for massive obesity, 16 underwent end-to-end 10"-10" jejunoileal bypass with drainage of the excluded small bowel into the transverse colon. If the gallbladder was found abnormal at surgery, cholecystectomy was carried out. There were three patients (two men and one woman, aged 31 to 39 yr) who developed the severe complication of pancreatitis in the postoperative phase. One patient developed severe upper abdominal pain which was diagnosed as acute pancreatitis; he recovered over a 10 day period. By dietary modifications and the elimination of alcohol, he remained well over a 12-month follow-up. The second patient to develop this complication died. Autopsy revealed hemorrhagic pancreatitis and retroperitoneal necrosis in the remnant of pancreas, with severe fatty degeneration of the liver. There was chronic cholecystitis, and several multifacetted stones in the gallbladder. His bile had been lithogenic two weeks prior to death. The third patient developed acute pancreatitis 5 months after the bypass surgery. Conservative treatment was used. One month later a cholecystogram revealed a nonfunctioning gallbladder with stones; a cholecystectomy was performed. Liver biopsies at the time of bypass surgery revealed mild to moderate fatty changes in these patients, and palpation of the gallbladders at the initial surgery suggested they were normal. If it can be shown that this complication is directly related to the intestinal bypass procedure used and not to preexisting gallbladder disease, then it is suggested that this method be dropped in favor of a less drastic bypass procedure.

6057 HYPERLIPOPROTEINEMIA AND ACUTE PANCREATITIS.

(Sp.) Carmena, R.; Ascaso, J.; Ferrando, J.; Fornes, J.; Gonzales-Bayo, E.; Bort, J. (Med. Fac., Valencia, Spain). *Rev. Esp. Enferm. Apar. Dig.* 45(3):269-280, 1975.

Case reports are presented for six patients (four women and two men, aged 23-63 yr) with acute pancreatitis associated with hyperlipoproteinemia. Acute pancreatitis was diagnosed on the basis of clinical symptoms and significantly increased serum amylase activities (four cases). In two patients, blood lipid levels were so high that they interfered with serum amylase determinations and false negative results were obtained; pancreatitis was diagnosed by increased urinary amylase activities in these two cases. Cholelithiasis was diagnosed in two patients; none were alcoholics. Familial hyperlipoprotenemia was present in three patients, two of whom were siblings. One female sibling had had five episodes of acute pancreatitis during the 4 yr previous; three of these episodes occurred during pregnancy. She was placed on a low-fat diet to prevent recurrences. Primary hyperlipidemia was diagnosed in four patients and secondary hyperlipidemia in two. The two patients with secondary forms had type V hyperlipidemia which disappeared 8 days after hospitalization. Determination of serum lipid fractions during the attack of acute pancreatitis showed that all six patients had increased serum cholesterol, triglyceride, phospholipid, and total lipid concentrations; chylomicrons were detected in three cases. Electrophoresis revealed that hyperlipidemia was type IV in two cases, type V in three and type II B in one. In addition to acute pancreatitis and hyperlipoproteinemia (type V), one patient was obese and had a familial form of diabetes which had been diagnosed 9 yr previously; 1 yr before admission he had had a myocardial infarction and an episode of acute pancreatitis. All patients responded to conservative therapy (nasogastric aspiration, parenteral fluids, analgesics, broad-spectrum antibiotics, etc.).

LIVER AND BILIARY TRACT

6078 LIVER FAILURE AND DRUG METABOLISM. *(E.)* Andreasen, P. B.; Ranek, L. (Rigshosp., Copenhagen, Denmark). *Scand. J. Gastroenterol.* 10(3):293-297, 1975.

The drug-metabolizing capacity of the liver (as measured by the metabolic clearance of antipyrine in patients with hepatic encephalopathy) was investigated in order to determine whether these patients have lower antipyrine clearance than non-encephalopathic patients with liver disease. Of 13 patients with hepatic encephalopathy, eight had acute hepatitis and five, cirrhosis. All subsequently developed stage III encephalopathy, and only one survived. A second group of patients comprised five persons with cirrhosis. Data for these first two groups of patients were compared to those obtained from 21 subjects without liver disease and 19 patients with biopsy-proven cryptogenic and alcoholic cirrhosis, all without signs of encephalopathy. The hepatic microsomal metabolism of antipyrine was measured in the 18 patients with encephalopathy before, during, and after hepatic encephalopathy. The antipyrine clearance measured in 13 patients during hepatic encephalopathy (4.6 ml/min) was significantly lower than that of five patients investigated 4 weeks before or after hepatic encephalopathy (9.6 ml/min). It is concluded that the clearance of antipyrine as a measure of quantitative liver function is substantiated by these data, and its use as a prognostic indicator of acute liver failure is suggested.

6079 ON THE DIAGNOSTICAL VALUE OF THE INDOCYANINE CLEARANCE IN CHRONIC DISEASES OF THE LIVER. *(E.)* Janev, P.; Zarzova, E. (I.P. Pavlov Higher Med. Inst., Plovdiv, Bulgaria). *Folia Med. (Plovdiv)* 16(3):157-161, 1974.

The diagnostic value of the indocyanine green clearance test was studied in 42 patients with diseases of the liver. Of these, eight had clinically decompensated liver cirrhosis; 18 had diffuse hepatic involvement (including chronic hepatitis, chronic cholangiohepatitis, and hepatic steatosis); five had primary and/or metastatic carcinomas; one had hyperbilirubinemia; four had cholecystic disease and six had other disease with no hepatic involvement. Of all patients tested for indocyanine green clearance, 29 (69%) were positive, as compared to 12% for SGOT and 3.8% for SGPT, for example, among other liver function tests performed at the same time. There was a close correlation between the gravity of the liver disease and the deviation in indocyanine green clearance indices, especially in cases of liver cirrhosis. The half-elimination probe and the elimination constant were established as the most sensitive indices. Due to the high diagnostic value of this test, the simple techniques necessary for its performance, and the lack of side effects, it is concluded that the indocyanine green clearance test should be ranked as one of the more valuable methods in the estimation of impaired liver function.

6080 ALOPECIA, ASCITES, AND INCOMPLETE REGENERATION AFTER 85 TO 90 PER CENT LIVER RESECTION. *(E.)* Starzl, T. E.; Putnam, C. W.; Groth, C. G.; Corman, J. L.; Taubman, J. (Univ. Colorado Sch. Med., Denver). *Am. J. Surg.* 129(5): 587-590, 1975.

The clinical course of a 19 yr-old female with a well-differentiated hepatoma who underwent 85-90% hepatectomy was presented. Hepatic tissue remaining after surgery consisted of a lateral portion of the left lobe. The patient was supported postoperatively by i.v. therapy including continuous albumin infusion (serum albumin>3 g/100 ml). The patient, however, developed ascites and subtotal alopecia within a week. At no time had the patient received cytotoxic chemotherapy. Daily low-grade fevers persisted for 2 months. Hyperbilirubinemia and depressed prothrombin time returned to normal about 1 month after surgery. The ascites was treated successfully with diuretics and the patient's hair eventually regrew. Serial 99mTc liver/spleen scans showed substantial but incomplete liver regeneration, which reached a maximum 6 months after resection. After 20 months, liver function was normal and there was no evidence of recurrent tumor.

6081 HEMANGIOMAS OF THE LIVER IN INFANTS: REVIEW OF DIAGNOSIS, TREATMENT AND COURSE. *(E.)* Slovis, T. L.; Berdon, W. E.; Haller, J. O.; Casarella, W. J.; Baker, D. H. (Columbia-Presbyt. Med. Cent., New York, N.Y.). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 123(4):791-801, 1975.

Clinical and roentgenologic findings were presented for six infants who presented with benign vascular liver tumors between the first day and third month of life. All had high cardiac output or frank congestive heart failure. Presenting signs also included abdominal mass or enlarging liver and cutaneous hemagiomas. I.v. urography, with total body opacification, showed abnormal liver findings in 3/6. 99mTc liver scans were abnormal in four patients. The most useful diagnostic test was arteriography, which showed hypervascular lesions and early venous runoff in all subjects. Four patients, who were managed non-surgically with digitalis, steroids and radiotherapy (150-600 rads) or combinations of these regimens were alive after 3 months to 2 yr. One patient died of congestive heart failure prior to initiation of therapy. The sixth patient underwent surgical excision and is alive 7 yr later. The successful medical management of these patients suggest that this mode of therapy should be used initially in infants who present with high output state or congestive heart failure and who have early draining hepatic veins on arteriography. Patients not in heart failure and without early draining hepatic veins should have a liver biopsy to rule out hepatoblastoma.

6082 THE POLYMERIZED ALBUMIN AND ANTI-ALBUMIN AUTOANTIBODIES IN PATIENTS WITH HEPATIC DISEASES. *(E.)* Lenkei, R.; Mota, G.; Dan, M. E.; Laky, M. ("Victor Babes" Inst., Bucharest, Romania). *Rev. Roum. Biochem.* 11(4):271-276, 1975.

Antibodies against polymerized albumin were detected in sera from four patients with liver disease and autoimmune disorders. Anti-polymerized albumin antibody was also detected in 65-95% of sera from 404 patients with various hepatic diseases including acute, chronic active and persistent hepatitis and cirrhosis. There was no correlation between the presence of hepatitis B antigen and anti-albumin antibody although 27-55% of albumin-antibody-positive patients were also hepatitis B antigen-positive. Anti-polymerized albumin was more commonly present, however, in patients with impaired liver function. It is suggested that anti-polymerized albumin antibody may be a useful test for liver function but may also contribute to false positive results when testing for hepatitis B antigen in certain patients.

6083 A COMPARISON OF SCANS AND ANGIOGRAMS IN SELECTING PATIENTS WITH HEPATOMAS FOR HEPATIC LOBECTOMY. *(E.)* Gammill, S. L.; Takahashi, M.; Jingu, K.; Stumpe, W.; Font, R. (Univ. Tennessee Med. Sch., Memphis). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 123(3):522-530, 1975.

The comparative abilities of ^{198}Au or ^{99m}Tc liver scan and selective hepatic angiography to predict operability were studied in 35 patients with hepatoma. Liver scan and angiography agreed regarding operability *versus* inoperability in 27 cases. In 23 cases, which were determined to be inoperable by both studies, inoperability was confirmed at laparotomy or autopsy. Three of the four patients in whom tumors were judged operable had tumor confined to one lobe at survey or autopsy; the fourth subject had microscopic metastases in an opposite lobe. Liver scan and angiography did not agree with respect to operability in eight patients, five of which were predicted correctly by angiography owing to its greater sensitivity in detecting neovascularization. These results indicate that combined liver scanning and selective hepatic angiography may be useful in predicting operability with respect to the primary lesion in patients with hepatoma.

6084 PATHOLOGICAL LIVER TESTS IN PATIENTS ON A LOW CARBOHYDRATE DIET. *(Ger.)* Lutz, W. (No affiliation). *Wien. Med. Wochenschr.* 125(18): 292-295, 1975.

SGOT, serum bilirubin and total plasma protein and protein fractions were determined in 190 patients with chronic liver disease who were placed on a low-carbohydrate diet (maximum of 12 g) with no restriction on protein and fat intake. No drugs were prescribed and no measures were recommended, e.g. abstention from alcohol, which might affect laboratory findings. Before institution of the diet, SGOT values fell into three groups: (1) from 13 to 20 mU in 126 cases, (2) from 21 to 40 mU in 50 cases, and (3) over 40 mU in 14 cases. SGOT values in group one normalized after patients had been placed on the diet for an average of 2 weeks, while those in groups two and three approached the normal range in most cases during the unspecified observation period. Leucine aminopeptidase values, determined in 23 patients, decreased over a 15 month period from a mean of more than 28 mU to a mean of 14 mU; normal values (below 20 mU) were attained after an average of ten months. Serum bilirubin values, which were initially elevated in 16 patients with no other signs of liver disease, decreased somewhat more slowly when carbohydrates were restricted. Using a method sensitive to 0.8 mg/100 ml bilirubin, the mean initial value of 1.6 mg/100 ml decreased almost to normal values (mean 1.0 mg/100 ml) over a 50-month period. The low-carbohydrate diet produced no appreciable changes in total plasma proteins or protein fractions. Since γ-globulin levels increased and ascites became more pronounced, the low-carbohydrate diet had to be abandoned in three cirrhotics.

6085 PALLIATIVE IRRADIATION FOR LIVER METASTASES. *(E.)* Turek-Maischneider, M.; Kazem, I. (Acad. Hosp., Cathol. Univ., Nijmegen, Netherlands). *JAMA* 232(6):625-628, 1975.

The palliative effect of liver irradiation in patients with symptomatic liver metastases is reported. All 11 patients (aged 11-56 yr) presented with upper abdominal pain, a palpable liver, and abnormal liver scans. The treatment was delivered by a telecobalt therapy unit, using two parallel opposing fields to cover the entire liver. Field size ranged from 15 x 20 to 20 x 24 cm, with leading-off of corners to match the field-to-liver shape and to minimize bowel irradiation. A daily dose of 150 rads calculated in the midliver plane was administered 5 times/week for 2-3 weeks. Response to treatment was evaluated according to the following categories: complete symptomatic relief, normalization or substantial improvement of liver function tests and liver scans (good); partial relief of symptoms, improvement of liver function tests, and reduction of the size of metastasis in the liver scans (moderate); and no symptomatic relief, no notable improvement of liver function tests, and no reduction in the size of metastasis in the liver scans (poor). Eight patients had good response; 2, moderate response; and 1 patient failed to respond to treatment. All patients tolerated the treatment and no deaths were attributed to liver irradiation. Three patients are alive at 4, 10, and 38 months, resp., after liver irradiation. It is concluded that radiation therapy is valuable for the treatment of symptomatic liver metastases, and is much safer than intrahepatic arterial infusion.

6086 THE HEPATORENAL SYNDROME: RECOVERY AFTER PORTACAVAL SHUNT. *(E.)* Ariyan, S.; Sweeney, T.; Kersten, M. D. (Yale Univ. Sch. Med., New Haven, Conn.). *Ann. Surg.* 181(6):847-849, 1975.

A case report is presented for a patient with the hepatorenal syndrome, a 78-yr-old man, admitted with cirrhosis of unknown etiology. On his first admission, he was noted to have tense ascites with 4+ pitting edema of the lower extremities. Hepatitis-associated antigen testing was negative; a liver scan showed a small liver with an enlarged spleen. He was placed on aldactone, digitoxin, a low salt and protein diet, and fluid restriction. Repeat liver biopsy showed fibrosis of the portal tracts. After several weeks, the ascites improved significantly, and he was discharged. One week prior to his second admission, he noticed increasing ascites and a 7-lb weight gain. Paracentesis revealed chylous ascites with 355 mg% lipids. Attempts at diuresis resulted in a rise in the blood urea nitrogen from 33 to 51. An enlarging umbilical hernia which was beginning to ulcerate was noted. Hepatic wedge pressure was 32 mm Hg; the i.v. cholangiogram was within normal limits and there was no hepatofugal flow. A successful side-to-side portacaval shunt was performed, and postoperatively, the hepatorenal syndrome was relieved. It is concluded that spontaneous recovery from the hepatorenal syndrome is rare; this patient is the 2nd case reported in the literature to recover from the hepatorenal syndrome following a surgical procedure to decompress the portal venous hypertension.

6087 ALPHA$_1$-ANTITRYPSIN DEFICIENCY AND HEPATIC CARCINOMA. *(E.)* Schleissner, L. A.; Cohen, A. H. (Harbor Gen. Hosp., Torrance, Calif.). *Am. Rev. Respir. Dis.* 111(6):863-868, 1975.

A patient with homozygous ZZ α_1-antitrypsin deficiency and severe emphysema, with a mixed carcinoma (hepatic and cholangiolar) of the liver in the absence of hepatic cirrhosis or fibrosis, was studied. When last admitted, the patient was in a respiratory coma. Serum alkaline phosphatase was 61.2 King-Armstrong U; neither serum α-fetoprotein nor hepatitis B antigen was detected, and there were no clinical signs of liver disease. On autopsy, the liver weighed 1,600 g and had a smooth capsular surface. The parenchyma was of usual consistency, displaying moderate passive congestion. Deep within the central portion of the right lobe was a firm, poorly delineated, whitish-tan mass measuring 6 cm in greatest diameter and surrounded by several smaller satellite lesions of similar description. Microscopic evaluation revealed hepatic parenchyma with normal ultrastructure. Intracellular inclusions in periportal hepatocytes were seen after periodic acid-Schiff stain. Malignant glandular structures were observed in the cholangiolar phase of the tumor. Because of the increasing frequency of hepatomas reported in patients with α_1-antitrypsin deficiency, it is suggested that a causal relation may exist.

6088 MANAGEMENT OF PRIMARY LIVER CELL CARCINOMA. *(E.)* Balasegaram, M. (Gen. Hosp., Kuala Lumpur, Malaysia). *Am. J. Surg.* 130(7):33-37, 1975.

An analysis of 352 cases of primary liver carcinoma is presented. The ratio of males to females was 4:1, and the patients ranged in age from 1 to 86 yr, with the majority aged 45-60 yr. Of the patients, 42 were admitted with acute abdomen after rupture of the hepatoma (15 of these died before any effective treatment could be carried out); 38 were admitted with bleeding esophageal or fundic varices associated with liver cirrhosis; and 52 had end-stage liver failure on admission. Of the total number of patients, 139 received no treatment: 34 left the hospital before treatment could be begun; 37 died of hemorrhage; and all 67 admitted with end-stage disease died within 2 weeks. Curative resection was attempted in 26 patients, and the results were: postoperative death (4); lost to follow-up (1); died within 1 yr (6); died within 2-3 yr (4); died within 3-4 yr (2); alive 2-3 yr later (4); and alive after 5 yr (5). Palliative treatment was attempted in the remaining 93 cases whose tumors were nonresectable. This included regional chemotherapy (25); complete hepatic dearterialization (60); and multiple dose therapy (60). Based on these data, it is suggested that attention be directed to detection of the definite causative factors of hepatic carcinoma, and perhaps more importantly, to the development of a good screening test to detect early carcinoma of the liver.

6089 ARTIFICIAL LIVER SUPPORT BASED ON HAEMOPERFUSION OF ADSORBENTS. *(E.)* Dunlop, E. H.; Weston, M. J.; Gazzard, B. G.; Langley, P. G.; Mellon, P. J.; Williams, R. (King's Coll. Hosp. Med. Sch., London, England). *Biomed. Eng. (NY)* 10(6):213-218, 1975.

The need for a device capable of performing the excretory functions of the liver during acute and chronic liver failure is discussed, and experience with an artificial liver support system is reviewed. Hemoperfusion through activated charcoal or Amberlite XAD-2 was tested in an animal model of acute liver failure. The model depends on surgically-induced ischemia, and, as such, the liver necrosis was irreversible. Of 35 patients treated by charcoal hemoperfusion, all of whom were in deep hepatic coma from fulminant liver failure, 16 recovered consciousness completely and 13 are now alive and well at home 18 months later. It is concluded that although the technology of adsorbent hemoperfusion is at the moment in its infancy, the subject provides unique opportunities for bioengineers and clinicians to develop new therapeutic measures for the treatment of liver failure and to improve existing methods for kidney failure and poisoning.

6090 HEMANGIOSARCOMA OF THE LIVER. SPECTRUM OF MORPHOLOGIC CHANGES AND CLINICAL FINDINGS.

(E.) Ludwig, J.; Hoffman, II, H. N. (Mayo Clin., Rochester, Minn.). *Mayo Clin. Proc.* 50(5):255-263, 1975.

Four cases of hemangiosarcoma of the liver and a brief review of the literature are presented, stressing features to enable the clinician and pathologist to make an earlier diagnosis. The patient group included 3 men and 1 woman, aged 36 (the woman) to 89 yr. The first case showed blood-filled cystic spaces in the liver lined by hemangiosarcoma cells. Vasoformative hemangiosarcoma tissue was seen to infiltrate the lumen of the hepatic vein. The final diagnosis was diffuse Kupffer cell carcinoma, of a nodular solid and microcystic type, with one small pulmonary metastasis, and ischemic hepatic necrosis; death was due to hepatic failure. The second case showed dilated hepatic sinuses lined by hyperchromatic hemangiosarcoma cells. The final diagnosis was a diffuse Kupffer cell sarcoma of the nodular and cystic type, without metastases, and possibly posthepatic cirrhosis. Death in this case was also due to hepatic failure. Hemangiosarcoma replacing the right lobe of the liver was seen in the 3rd case, with a small satellite nodule in the left lobe. The diagnosis was a circumscribed, nodular solid, and microcystic type of Kupffer cell sarcoma. Death was due to bronchopneumonia. Histologic examination of the liver in the 4th case showed multiple blood-filled cysts. An autoradiograph showed the typical α-ray tracks from thorium dioxide deposit (this patient had received 20 ml of thorotrast into the right carotid artery). Final diagnosis was a low-grade Kupffer cell sarcoma, of the diffuse cystic type, with thorium dioxide storage in the liver and lymphatic organs. Death came from exsanguination of the hepatic tumor. Analysis of these cases and a review of the literature indicated that these tumors are either predominantly cystic and fairly well-differentiated or are more solid and poorly differentiated. Well-differentiated tumors may resemble peliosis hepatitis or other benign conditions. It is concluded that the concept of Kupffer cell sarcoma is weakened by the fact that primary and secondary hemangiosarcomas in the liver, including their sinusoidal spread, are histologically indistinguishable.

6091 HEPATOCELLULAR CARCINOMA. A CLINICAL AND PATHOLOGICAL STUDY OF 33 CASES. *(E.)*

Tsakraklides, V.; Templeton, A. C.; Estensen, R.; Good, R. A. (Dep. Pathol., Univ. Minnesota, Minneapolis). *Minn. Med.* 58(6):450-453, 1975.

An analysis of 33 cases of hepatocellular carcinoma seen at postmortem at the University of Minnesota Hospitals is presented; the histological features, metastatic patterns, diagnostic problems, and relation to cirrhosis are discussed. Of 12,070 case records examined, 33 hepatocellular carcinomas were found, comprising 0.27% of the autopsies recorded in an 18-yr period. All were caucasian, and 73% were male, with the peak incidence in the 6th, 7th, and 8th decades. The representing signs and symptoms were abdominal pain and discomfort in 15 cases, hepatomegaly in 6, jaundice in 5, and nausea and vomiting in 4. Hematemesis was the presenting symptom in 3, fatigue and weight loss in 2, and fever of unknown etiology in 2. The diagnosis was prior to death in 16 cases, and only at autopsy in the remaining 17. The average duration from onset of symptoms to death was 5.5 months; the longest interval was 18 months. Death was caused by gastrointestinal bleeding in 10 cases, hepatic coma in 9, pneumonia in 7, hepatorenal failure in 5, and was operative or postoperative in 2. Cirrhosis was an associated disease in less than half of these patients. The incidence of hepatocellular carcinoma appeared in this geographical area to be rising slowly, and the incidence of cirrhosis as well as the incidence of liver carcinoma in cirrhotics did not significantly increase. The data suggest that the patients at particular risk were elderly males with coarse nodularity of the liver.

6092 ENZYME REPLACEMENT IN NIEMANN-PICK DISEASE BY LIVER HOMOTRANSPLANTATION. *(E.)*

Daloze, P.; Corman, J.; Bloch, P.; Delvin, E. E.; Glorieux, F. H. (Notre Dame Hosp., Univ. Montreal, Canada). *Transplant. Proc.* 7(1):607-610, 1975.

The feasibility of long-term enzyme replacement by liver homotransplantation as evaluated in a recipient afflicted in Niemann-Pick disease type A is reported. Hepatomegaly in an otherwise healthy 4-month old boy led to the early diagnosis of Niemann-Pick disease that was later confirmed by the demonstration of sphingomyelinase deficiency in WBC and cultured skin fibroblasts. Psychomotor retardation and massive hepatosplenic involvement were evident at age 1 yr. Orthotopic liver transplantation was performed at age 2 yr. Muscular activity increased, expression of the face became more mobile, and seizures that were frequent in the early postoperative period slowly became scarcer without specific medication. After transplantation, sphingomyelin did not reaccumulate in the grafted liver and could not be detected in urine. Indirect evidence appears to indicate that lipid deposits are beginning now to regress in some tissues, such as lungs and retina. Sphingomyelinase has been detected not only in the graft but also in several physiologic fluids including the cerebrospinal fluid. These observations raise the possibility for stabilization or even cure of some congenital enzymatic deficiencies by organ transplantation, when the deficient enzyme is not available by other means.

6093 REYE'S SYNDROME: EPIDEMIOLOGIC AND VIRAL STUDIES, 1963-1974.

(E.) Linneman, Jr., C. C.; Shea, L.; Partin, J. C.; Schubert, W. K.; Schiff, G. M. (Univ. Cincinnati Coll. Med., Ohio). *Am. J. Epidemiol.* 101(6):517-526, 1975.

The experience with Reye's syndrome in a single medical center from 1963-1974 is reported; only those cases shown to have fatty liver were included in the study. During this time period, 58 children with Reye's syndrome confirmed by liver biopsy were treated at this center. Cases were clustered in the winter and spring with the peak in February and March. These coincided with the occurrence of influenza and, numerically, were associated more closely with influenza B than with influenza A. Of the 58 cases, 6 were associated with chickenpox. From 1963-1971, before the beginning of a systematic epidemiologic and virologic study, 26 children with Reye's syndrome were seen. Viral infection was documented in either the patient or a contact in only 19% of those studied. Between 1971-1973, after the study was initiated, 16 cases of Reye's syndrome were diagnosed and viral infection was confirmed in 56% of these. In 1974, an epidemic of Reye's syndrome occurred during an influenza epidemic and viral infection was found in either the patient or a contact in 81% of 16 cases. During this study no significant environmental toxic exposures could be identified. Most children had taken aspirin and other medications, and 7 children had a history of excessive aspirin ingestion. This study demonstrates that an association with viral infection can be proven in the majority of cases of Reye's syndrome when an intensive investigation is undertaken.

6094 ALPHA-1-FETOPROTEIN AND THE HEAT STABLE ALKALINE PHOSPHATASE IN SOME LIVER DISEASES.

(E.) Zizkovsky, V.; Kordac, V.; Stepan, J.; El'gort, D. N. (Fac. Gen. Med., Charles Univ., Prague, Czechoslovakia). *Acta Hepatogastroenterol. (Stuttg.)* 22(2):92-97, 1975.

The presence of α_1-fetoprotein, heat-stable alkaline phosphatase, and Australia antigen (HB_sAg) was examined in 103 patients with porphyria cutanea tarda, 300 patients with cirrhosis, and 18 patients with primary liver carcinoma. Heat-stable alkaline phosphatase was detected in 46% of patients with porphyria cutanea tarda and in 61% of patients with primary liver carcinoma. α_1-Fetoprotein was detected in 61% of patients with primary liver carcinoma and in 2 patients with porphyria cutanea tarda in whom primary liver carcinoma was later proved. The simultaneous occurrence of α_1-fetoprotein and heat-stable alkaline phosphatase was found in 50% of cases with primary liver carcinoma. Neither the patients with porphyria cutanea tarda nor those with cirrhosis were HB_sAg-positive. HB_sAg could be detected in only 1 patient with α_1-fetoprotein-positive carcinoma of the liver. The finding of the heat-stable alkaline phosphatase in the blood sera of 46% of patients with porphyria cutanea tarda supports the hypothesis that this disease is a possible precancerous state. However, since the detection of the heat-stable alkaline phosphatase may be caused by the enzyme stabilized with one of the metabolites originating in porphyria cutanea tarda, the question requires further research.

6095 PATHOLOGY OF THE LIVER IN REYE'S SYNDROME.

(E.) Svoboda, D. J.; Reddy, J. K. (Univ. Kansas Med. Cent., Kansas City). *Lab. Invest.* 32(5):571-579, 1975.

Case reports are presented for 6 patients (4 men and 2 women, aged 4-16 yr) with Reye's syndrome, of whom 4 died. Needle liver biopsy specimens were obtained from all patients either shortly before death or during recovery from several hours of coma. Fixed and stained portions were examined under the light and electron microscopes. Light microscopy revealed that inflammation and necrosis of liver cells were especially prominent in fatal cases. Contrary to previous reports, electron microscopy indicated that aside from a loss of matrix dense granules, alterations in mitochondrial structure were minimal or absent. Although an increase in the number of liver cell microbodies has previously been reported, no such increase was apparent in the present study. The most unusual ultrastructural change in microbodies in the present study was the presence of noncrystalline cores in the matrix. No ultrastructural features distinguished patients who died from those who survived. Although derangement of mitochondrial function may be important, it is concluded that such derangement in the pathogenesis of Reye's syndrome is not necessarily reflected in mitochondrial ultrastructure.

6096 GLUCOSE INTOLERANCE AFTER MASSIVE LIVER RESECTION IN MAN AND OTHER MAMMALS.

(E.) Ida, T.; Ozawa, K.; Honjo, I. (Fac. Med., Kyoto Univ., Japan). *Am. J. Surg.* 129(5):523-527, 1975.

The relation between changes in glucose tolerance and in mitochondrial phosphorylative activity was studied after massive liver resection. In rabbits 24 hr after hepatectomy, when the phosphorylative activity in the mitochondria of the remnant liver was enhanced maximally, the blood glucose level did not increase significantly after glucose administration (2 g/kg). When the phosphorylative activity decreased to a submaximal level 48 hr after hepatectomy, the blood glucose level increased gradually but without a return to normal. About 6 weeks after partial hepatectomy, mitochondrial function gradually returned to normal levels and the glucose tolerance test results returned to within normal limits. The changes in the glucose tolerance tests in rabbits were also observed in Wistar rats and in a 27-yr-old man hepatectomized for blunt abdominal trauma. The return to normal of the glucose tolerance test results, however, was more rapid in rats: 3 hr after partial hepatectomy, the fasting blood glucose was at a hypoglycemic level; after 24 hr, the level increased to more than 150 mg/100 ml; and after 3 days, the glucose tolerance patterns returned to normal. The return of test results to normal in the patient was remarkably delayed: p.o. glucose

LIBRARY U. OF

tolerance testing, 50 g, was carried out at 14, 44, and 90 days, postoperatively; values did not return to normal until the second and third tests. Based on these data, it is suggested that the glucose tolerance test is very useful in evaluating the stage of regeneration in the liver remnant after massive liver resection.

6097 CORTISOL METABOLISM IN CHRONIC LIVER DISEASE. *(E.)* McCann, V. J.; Fulton, T. T. (R. Victoria Hosp., Belfast, Northern Ireland). *J. Clin. Endocrinol. Metab.* 40(6):1038-1044, 1975.

To further evaluate the effects of impaired degradation of cortisol, various parameters of cortisol metabolism were measured in 39 patients (22 men and 17 women, aged 13-74 yr) with chronic liver disease. These parameters included total and nonprotein-bound plasma cortisol measured as 11-hydroxycorticoids at intervals during the day, urinary excretion of cortisol, corticosteroid-binding globulin, and cortisol excretion rate. The group of patients included persons with active chronic hepatitis (9), persistent hepatitis (2), cryptogenic or postnecrotic cirrhosis (15), and alcoholic cirrhosis (13). The mean plasma total 11-hydroxycorticoids (11-OHCS) was lower in patients than in controls, although the difference was not statistically significant, and the normal circadian rhythm was maintained. However, in patients with chronic liver disease, a greater proportion of the 11-OHCS was in the nonprotein-bound state, resulting in an elevation of this fraction. Corticosteroid-binding globulin was lower in patients than in controls, although the difference was not statistically significant. Urinary cortisol excretion was significantly reduced, as was excretion of 17-ketosteroids. The cortisol secretion rate was normal. The elevation of nonprotein-bound 11-OHCS represents a resetting of the pituitary-adrenal feedback mechanism in these patients. It is suggested that elevation of plasma nonprotein-bound 11-OHCS, resulting from impaired metabolism and reduced protein binding of cortisol in patients with hepatic disease, may explain the features of endogenous hypercorticsm seen in such patients. Moreover, in the presence of impaired steroid metabolism and reduced protein binding, these patients may exhibit an increased sensitivity to corticosteroid therapy, and therefore administration of a reduced dosage may be advisable.

6098 LIVER PATHOLOGY IN ALPHA$_1$-ANTITRYPSIN DEFICIENCY: A REVIEW. *(E.)* Cohen, C. (South African Inst. Med. Res., Johannesburg). *S. Afr. Med. J.* 49(21):849-852, 1975.

The association of liver disease with alpha$_1$-antitrypsin (AAT) deficiency (AATD) is reviewed. The lowest serum levels of AAT, a low-molecular weight glycoprotein synthesized in the liver, are found in persons with the homozygous Z phenotype, normal individuals exhibiting the homozygous M phenotype. Twenty percent of Pi-type ZZ AATD infants present with a cholestatic type of neonatal hepatitis and develop a slowly progressive cirrhosis, and most die before reaching adulthood. Cirrhosis develops in about 10% of adult Pi ZZ homozygotes, coexistent emphysema occurring in most such individuals. In adults, primary hepatocellular and cholangiocellular carcinomas are frequently reported but are usually unsuspected during life. Specific globules resulting from the accumulation of a type of AAT are noted in the periportal liver cells of over 80% of homozygous and heterozygous Z AATD patients; liver disease is not always present. These globules are usually intracellular and increase in number and width with age. In infants, the percentage of liver cells containing globules is related to Pi-type and inversely related to the serum AAT concentration, but there is no relation to clinical state, liver cirrhosis, emphysema, or normal status. The defect in AATD resulting in the accumulation of these globules appears to reside in the liver. It is unlikely that they are directly hepatotoxic, although they may render the liver more susceptible to damage by other factors. An infectious factor has been suggested but none has been confirmed; an additional metabolic or nutritional factor has also been suggested. AATD infants have low birth weights, suggesting onset of liver disease in the fetus. The prognosis for patients with the neonatal hepatitis syndrome and Pi ZZ phenotype does not appear to be worse than for patients with the syndrome and normal serum AAT. Liver biopsies are of value in indicating or confirming AATD and in making an early diagnosis of hepatocellular carcinoma in AATD patients. Repeat liver biopsies are also of use in the follow-up of AATD patients.

6099 SURVIVAL OF PATIENTS WITH UNTREATED LIVER METASTASES FROM COLORECTAL CANCER. *(E.)* Baden, H.; Andersen, B. (Bispebjerg Hosp., Copenhagen, Denmark). *Scand. J. Gastroenterol.* 16(1):221-223, 1975.

The effect of removal of the primary tumor on colorectal cancer patients with untreated liver metastases was studied. In October 1973, the survival status of 105 such patients, who had had the primary tumor removed between October 1962 and December 1972, was evaluated. The median survival time in this group was 10 months, nine patients being alive 108, 96, 93, 87, 56, 29, 18, 17, and 11 months after surgery. Among the nine patients still alive, the livers were definitely without metastases in two cases and their presence or absence was unconfirmed in the other seven. Of those who died, liver metastases were confirmed by autopsy in 77 cases and autopsies were not performed in the other 19 cases. These data, in conjunction with previous reports, indicate that the median survival time with untreated liver metastases is between 6 and 10 months after extirpation of the primary colorectal tumor; this value is considerably higher than would be expected in unselected series of liver metastases, suggesting that prognosis is better in patients who have had the primary tumor excised.

6100 ISOLATED LIVER NODULES. *(E.)* Shojania, N. G.; Hogg, G. R. (Univ. Manitoba, Med. Coll., Winnipeg, Canada). *Gastroenterology* 69(1):28-34, 1975.

A series of seven cases of isolated liver nodules is reviewed. Two were encountered at surgery and five at autopsy. Autopsy incidence was slightly less than one in 1000 over a 6 yr period. In no case were there symptoms or signs relating to the nodule. Most cases had single nodules, but three cases had three separate nodules each. All 13 nodules were spherical, measured 0.5 to 9.5 cm in diameter, were pale to yellow in color and were unencapsulated. Light microscopy showed histological features resembling regenerating nodules in cirrhotic liver in 11 nodules; two nodules were fatty in makeup. Except for the nodular areas, the livers were all grossly and histologically normal. The nodules showed a visible scarcity of red cells, suggesting that the nodules were relatively ischemic. This may have resulted from abnormal blood flow. The nodules typically contained prominent vessels not associated with the portal tracts or central veins. They had abnormal, unevenly thickened walls composed mainly of fibrous tissue with a few sparse muscle fibers. The fatty changes in two of the nodules also supported ischemia as the etiological factor. It is suggested that the amount of fatty change parallels the degree of ischemia, or that the fatty nodules are the earliest ischemic effect, which may later undergo focal septal fibrosis and regenerative activity.

6101 HUMORAL AUTOIMMUNE PHENOMENA IN LIVER DISEASE. *(Ger.)* Berg, P. A. (Med. Clin., Univ. Tubingen, Germany). *Z. Gastroenterol.* 13(suppl.):257-263, 1975.

Of 105 patients with acute viral hepatitis, 78 were positive for hepatitis B antigen (HBAg). Immunofluorescence studies showed that, at onset, 80% had anti-smooth muscle antibodies, 35% had antibodies to vascular endothelium, and 12% had antinuclear antibodies; none of these patients had antimitochondrial antibodies. Antibodies to vascular endothelium occurred only in patients with blood group O. They were of the IgG type and reacted with an antigen related to blood group substance A. These antibodies occurred either in association with HBAg or, in some cases, appeared only after the patients became HBAg-negative. In contrast to anti-smooth muscle antibodies, antibodies to vascular endothelium persisted for some time after acute symptoms had subsided; they were absent in patients with autoimmune diseases. Antinuclear antibodies were present in low titers and, in most cases, reacted only with heterologous tissue. Both antinuclear antibodies and anti-smooth muscle antibodies were present in only 10-20% of HBAg-positive patients with chronic aggressive hepatitis. Antibodies to vascular endothelium were found in 30-40% of patients with blood group O, but were present in 50% of those with cryptogenic cirrhosis. Patients with autoimmune phenomena were defined as HBAg-negative and HB antibody-negative who also had high titers of antinuclear antibodies in the presence or absence of anti-smooth muscle and antimitochondrial antibodies. The simultaneous presence of antinuclear and anti-smooth muscle antibodies in titers above 1:40 suggests lupoid hepatitis with or without cirrhosis. Antimitochondrial antibodies occur in more than 95% of all patients with primary biliary cirrhosis, and the association of these antibodies with antinuclear antibodies indicates the simultaneous existence of an inflammatory, autoimmune process in both the bile ducts and hepatic parenchyma. A very rare form of chronic aggressive hepatitis, which occurs in only one case in 800, is associated with antimicrosomal antibodies. In addition to chronic aggressive hepatitis resulting from viral infection, drug-induced forms are found in which high antibody titers are present, but antibodies disappear after discontinuation of use of the drug.

6102 METABOLISM OF LITHOCHOLATE IN HEALTHY MAN. I. BIOTRANSFORMATION AND BILIARY EXCRETION OF INTRAVENOUSLY ADMINISTERED LITHOCHOLATE, LITHOCHOLYLGLYCINE, AND THEIR SULFATES. *(E.)* Cowen, A. E.; Korman, M. G.; Hofmann, A. F.; Cass, O. W. (Mayo Clin., Rochester, Minn.) *Gastroenterology* 69(1):59-66, 1975.

The metabolism of i.v. administered radiolabeled lithocholate, its glycine conjugate (lithocholylglycine), its sulfate (sulfothiocholate), and its sulfated glycine conjugate (sulfolithocholylglycine) in healthy subjects is reported. Lithocholate radioactivity was excreted rapidly, predominantly in bile. The excreted radioactivity had the chromatographic properties of glycine and taurine conjugates of lithocholate, of which 60% were sulfated. Lithocholylglycine also was excreted rapidly, predominantly in bile, and 60% of the excreted radioactivity was sulfated. Sulfolithocholate radioactivity was only partially conjugated (about 60%) in association with biliary excretion. Sulfolithocholylglycine was excreted unchanged in bile. Neither sulfated derivative showed appreciable excretion in urine, although both were excreted more slowly in bile than unsulfated free or conjugated lithocholate. The data suggest that unconjugated lithocholate, which is absorbed, is completely conjugated and partially sulfated before excretion, which occurs exclusively in bile. Since sulfation is not complete, some unsulfated lithocholate is always present in bile. It is concluded that this conjugated but unsulfated lithocholate, if reabsorbed, would be again partially sulfated during its next enterohepatic circulation.

6103 PARTIAL DEFICIENCY OF HEPATIC GLUCOSE-6-PHOSPHATASE IN AN ADULT PATIENT. *(E.)* Stamm, W. E.; Webb, D. I. (Univ. Washington Affil. Hosp., Seattle). *Arch. Intern. Med.* 135(8):1107-1109, 1975.

A case of partial hepatic glucose-6-phosphatase deficiency in a 40-yr-old woman is described. The manifestations in childhood were mild and unrecognized, consisting only of frequent epistaxis and bruising. Beginning at age 14, the patient suffered episodes of acute arthritis involving a variety of joints; except for persistent malaise and fatigue, the patient was asymptomatic between attacks. Consanguinity was not present; she had six normal siblings and bore three healthy children of her own. She was of normal intelligence. Although blood glucose levels were low, actual hypoglycemia was not documented. The constellation of persistent acidosis, hyperlacticacidemia, hypercholesterolemia, hypertriglyceridemia, and hyperuricemia was repeatedly demonstrated over a period of several years. Unavailability of hepatic glucose-6-phosphate was demonstrated by a blunted hyperglycemic response to i.m. epinephrine and by a lack of blood sugar elevation following i.v. galactose. Other symptoms included bilateral arcus senilis and xanthelasma, s.c. tophi on the arms and legs, hepatic dullness, and decreased range of motion, synvovial thickening, s.c. nodules, and/or crepitus at the knees, elbows, ankles, wrists and small joints of the hands. A percutaneous liver biopsy demonstrated normal hepatocellular architecture with increased amounts of normally staining positive material. Partial glucose-6-phosphatase activity in this patient may explain her benign childhood course, emphasizing that patients with this deficiency may escape diagnosis during childhood, particularly if symptoms are mild or unrecognized. When acute gouty arthritis and tophaceous gout occur in an adolescent or young adult, the diagnosis of glucose-6-phosphatase deficiency should be considered.

6104 MORPHOLOGICAL CHANGES IN THE LIVER IN METABOLIC DISORDERS. *(Ger.)* Wohlgemuth, B. (Dep. Med., Karl Marx Univ., Leipzig, Germany). *Dtsch. Z. Verdau. Stoffwechselkr.* 34(1):17-22, 1974.

Metabolic diseases affecting the liver result in deposition of material foreign to liver cells or in deposition of nonphysiological quantities of substances normally found there. Mild forms of toxic parenchymal damage are characterized by localized cellular necrosis, steatosis and jaundice in addition to changes in metabolic activation (anisocytosis and anisokaryosis, increase in the size of nucleoli, increase in the number of bi- and multinuclear hepatocytes, and changes in parenchymal structure). Kupffer cells are activated but show no signs of proliferation. In more severe damage the centrilobular areas are affected and necrosis of groups of cells, more marked steatosis, and leukocyte infiltration are observed. Cholestasis is occasionally present and is generally manifested by bile thrombi. The most severe form of parenchymal damage is dystrophy in which the entire liver becomes necrotic and there is no evidence of inflammation. The most common types of endogenous and exogenous metabolic diseases affecting the liver are briefly outlined.

6105 BILE ACIDS IN THE BLOOD AND URINE OF JAUNDICED AND NONJAUNDICED PATIENTS WITH VARIOUS LIVER DISEASES. *(Ger.)* Wildgrube, H. J.; Dittmann, K.; Erb, W. (Cent. Intern. Med., Univ. Frankfurt/Main, Germany). *Verh. Dtsch. Ges. Inn. Med.* 80:448-450, 1974.

Sulfate esters of bile acids were extracted from blood and urine specimens taken from 50 patients with compensated cirrhosis and 20 with hepatic metastases. The extracts were then fractionated on Sephadex LH 20, and sulfated bile acids were separated by gas-liquid chromatography of their trifluoro acetylated methyl esters on 3% QF-1. Patients with compensated cirrhosis had no evidence of jaundice (serum bilirubin levels lower than 1.5 mg/100 ml) or ascites, and none of the patients with hepatic metastases had primary tumors in the liver or biliary tract. The concentration of sulfate esters of blood bile acids in compensated cirrhosis ranged from 2 to 110 μM/l (mean 25.4 μM/l), while free and conjugated bile acid concentrations ranged form 7 to 130 μM/l (mean 31.8 μM/l). No significant correlation was found between these forms of bile acids. Most of the bile acids excreted in the urine of cirrhotics were in the form of sulfate esters. The rate of excretion averaged 0.84 μM/24 hr (maximum 2 μM/24 hr), and the content of free and conjugated bile acids was usually lower (around 0.68 μM/24 hr). These findings contrast with those observed previously in cirrhotics with epithelial or portal decompensation in whom both bile acid fractions were significantly increased. In both blood and urine, the concentration of cholic acid was significantly decreased. Patients with hepatic metastases had jaundice and increased concentrations of bile acids in their blood. However, the relative percentage and absolute concentrations of sulfated bile acids were completely independent of serum bilirubin concentrations. Many patients with high serum bilirubin concentrations (above 12 mg/100 ml) had relatively low sulfated bile acid concentrations, and these concentrations varied greatly during the day. These findings indicate that formation of sulfate esters of bile acids is not a protective mechanism occurring only in cholestasis.

6106 GRANULOMAS OF THE LIVER. *(E.)* Neville, E.; Piyasena, K. H. B.; James, D. G. (R. North. Hosp., London, England). *Postgrad. Med. J.* 51(596):361-365, 1975.

Clinical, radiological, and immunological data were reviewed in 138 cases of biliary hepatic granuloma, for factors helpful in defining etiology and prognosis, and for determining whether granulomatous hepatitis is a distinguishable condition. Of the patients, 75 had sarcoidosis, 26 had primary biliary cirrhosis, 23 had miscellaneous known disorders and 14 had idiopathic disease. Of the sarcoidosis group, 68% presented at 20-40 yr of age with no sex predilection, while 81% of the cirrhosis group presented at 30-50 yr and all but one were female. The miscellaneous group was predominately female, while the idiopathic group was mostly males over 50 yr of age. The sarcoidosis and cirrhosis groups presented with typical symptoms of the respective conditions. Liver function tests were most commonly abnormal in the cirrhosis and miscellaneous groups. Aspartate transaminase activity was most frequently abnormal (elevated in 85% overall), followed by alkaline phosphatase activity (62%). An abnormal chest radiograph was found in 55% of all patients, 84% of these in the sarcoidosis group. The Kveim-Siltzbach skin test was positive in 72% of the sarcoidosis group, but in no other group. Autoantibodies were most common in the cirrhosis group (79%). In 46 of the sarcoidosis group followed up for 1 to 14 yr, 76% showed complete resolution, and 17% had chronic, persistent sarcoidosis. Of the cirrhosis group after a 1 to 10 yr follow-up, 30% died, 12% developed portal hypertension, and all had progressively abnormal liver function tests. Of the 14 idiopathic patients, five recovered spontaneously in 2 to 4 yr, and one recovered with anti-tuberculous chemotherapy. It is concluded that clinical picture, X-ray, blood, skin and microbiological tests result in diagnosis of cause in 90% of the cases; the term granulomatous hepatitis should be reserved for the undiagnosed 10% until follow-up reveals a more definitive cause.

6107 BENIGN HEPATOCELLULAR TUMOURS. *(E.)* Sorensen, T. I. A.; Baden, H. (Gentofte Hosp., Univ. Copenhagen, Denmark). *Scand. J. Gastroenterol.* 16(1):113-119, 1975.

The clinical, histological, and therapeutic experience in 250 cases of benign hepatocellular tumors is reviewed and an approach to the management of such tumors is suggested. Of all benign tumors and tumor-like lesions containing liver cells, only focal nodular hyperplasia (FNH), liver cell adenoma (LCA), and nodular liver cell adenoma are considered benign hepatocellular tumors. Of the 250 cases collected from Anglo-Saxon, German, French, and Scandinavian literature between 1923 and 1974, there were 141 cases of FNH, 69 cases of LCA (including 11 cases of nodular liver cell adenoma), and 40 unclassified tumors (UT). The frequency of these tumors may be increasing. In the clinical series, the female:male ratio was 3.7, with the incidence being highest among females in the fertile years and males between 0 and 30 yr; in the necropsy series, the female:male ratio was 1.6 and the median age was 50 yr. Most FNH were 4-7 cm, firm, and found in the left lobe, while most LCA were 8-15 cm, soft, and found in the right lobe. By light and electron microscopy, the cells and microstructures of the tumors resemble normal hepatic tissue. FNH is not potentially malignant, although LCA may be. Thirty-five percent of the FNH patients and 44% of the LCA patients presented with symptoms of moderate pain in the upper right abdominal quadrant, abdominal mass, and/or gastrointestinal upset. Complications, generally acute abdominal disease caused by hemorrhage and necrosis of the tumor, were the first manifestations in 38% of the LCA and none of the FNH patients. A hepatic tumor was preoperatively diagnosed by radiography, arteriography, and/or scintigraphy in 20% of the patients, and a preliminary diagnosis by biopsy was reported in 40 cases, with frozen section in 24, and with paraffin section in 16. Local resection or hemihepatectomy was used to remove the tumor entirely in 148 patients and partially in 34 patients. Total removal of the tumor generally cured the patient, and the outcome was good in 50% or more of the patients after partial removal. In patients with FNH, removal is not indicated if a major hepatic resection is required but is both effective and justified in the presence of complications or symptoms requiring treatment. In cases of LCA, the tumor should be removed. Enucleation of benign hepatocellular tumors is not advised and hormonal contraception should be discouraged in female patients. A 5-yr follow-up with ultrasonic scanning or scintigraphy is recommended.

6108 HEPATOSIS OF PREGNANCY. A CLINICAL STUDY OF 107 PATIENTS. *(E.)* Ylostalo, P.; Ylikorkala, O. (Dep. Obstet. Gynaecol., Univ. Oulu, Finland). *Ann. Chir. Gynaecol. Fenn.* 64(2):128-134, 1975.

The clinical experience in 107 patients with hepatosis of pregnancy is reported and compared with that in 61 controls with normal pregnancies. All cases were evaluated with regard to the date and duration of delivery, birth weight and condition of the neonate, and weight of the placenta. The hepatosis group was also given liver function tests and a glucose tolerance test, and the urinary estrogen levels were measured daily. The duration of the first stage of delivery was slightly ($p < 0.05$) shortened in the hepatosis group, and delivery took place more than 2 weeks earlier in this group than in the controls. There were two fetal deaths in the hepatosis series. The average Apgar scores at 1 and 15 min were slightly but significantly lower in the hepatosis group than in the controls, with no differences in scores according to sex. In addition, the average birth weight was slightly lower in the hepatosis group, and 11.9% of the infants in this group weighed less than 2.5 kg at birth. The absolute and relative placental weights did not differ between the two groups, although there were histologically evident maturing defects in the placenta in 20 of the 58 hepatosis cases studied. The liver function tests confirmed the cholestatic nature of the disease, yielding elevated aminotransferase, alkaline phosphatase, and bilirubin levels. The thymol turbidity test was within normal limits, indicating that the hepatosis series may have included cases of hepatitis. Neither glucose nor daily urinary estrogen levels differed significantly from normal. Fifty-five percent of the multiparous hepatosis patients had suffered from this disorder during earlier pregnancies. The fetal survival rate in hepatosis of pregnancy can be considerably improved by intensive hospital treatment during pregnancy.

6109 ON THE EXISTENCE OF INTRAHEPATIC BILE DUCT SHUNTS. *(E.)* Aiginger, P.; Polterauer, P.; Tizian, C. H. (Univ. Vienna, Med. Sch., Austria). *Anat. Embryol.* 147(1):111-116, 1975.

A combined scintigraphic-radiological method was used to study the existence of intrahepatic shunts between the bile ducts of the right and left duct systems in 28 human autopsy specimens. The average age at death was 39 yr and there were equal numbers of males and females. The proximal section of the common bile duct was exposed, and meglumine diatrizoate and Tc-99m Pertecnetat were injected in different orders into the left or right intrahepatic bile duct system after application of a water-tight ligature immediately proximal to the hepatic bifurcation. In all cases, passage of the injected substances into the periphery was observed. Although very small biliary capillaries were visualized, the substances did not appear to enter the contralateral bile duct system. Similarly, intralobular shunts were not observed following bilateral drainage of the caudate lobe. Despite the great difference in viscosity in the substances used, identical results were obtained with the combined radiologic-scintigraphic method. On the basis of these results, no conclusions regarding function can be made.

6110 REYE SYNDROME: A CORRELATED ELECTRON-MICROSCOPIC, VIRAL, AND BIOCHEMICAL OBSERVATION. *(E.)* Tang, T. T.; Siegesmund, K. A.; Sedmak, G. V.; Casper, J. T.; Varma, R. R.; McCreadie, S. R. (Milwaukee Child. Hosp., Wis.). *JAMA* 232(13): 1339-1346, 1975.

Liver biopsy specimens from two patients with Reye syndrome were examined ultrastructurally and for viral particles and urea-cycle enzyme activity. The patients, 10- and 14-yr-old boys, were hospitalized with symptoms of upper respiratory tract infection, persistent vomiting, delerium, combative behavior, and hyperammonemia. The first patient died 15 hr after admission and autopsy speciments of lung, liver, and heart were obtained. The second patient recovered and was discharged after nine days; a liver biopsy specimen was obtained on the second day after hospitalization. In addition, urine, serum, and throat swab samples were obtained from both patients. The liver specimens were examined by electron microscope and attempts were made to isolate viral particles from the other tissues and urine and throat specimens after inoculation into cultures of human foreskin fibroblasts, WI-38, HeLa, HEp-2, and grivet monkey kidney cells. The serum samples were tested for antibodies to various viruses by microcomplement fixation and hemagglutination inhibition procedures and were assayed for hepatic ornithine transcarbamoylase, hepatic carbamoyl phosphate synthetase, arginase, and glycogen. The hepatocytes from both patients contained a large amount of glycogen and degenerating mitochondria. Numerous herpes-like virus and myxovirus/paramyxovirus particles were seen in the spaces of Disse and sinusoids, and there was a leakage of glycogen granules into these areas. Cytomegalovirus was isolated from the heart and liver speciments of the first patient, but no particles were isolated from the liver specimen of the second patient or urine specimens of either patient. The results were supported by the serologic tests, and serum hepatic ornithine transcarbamyolase levels in both patients were subnormal. The pathogenesis in Reye syndrome therefore appears to involve an initial synergistic insult to the liver by mixed types of viruses and subsequent breakdown of the urea cycle, Krebs cycle, and possibly other hepatic functions.

6111 FATTY METAMORPHOSIS IN PATIENTS WITH JEJUNOILEAL BYPASS. *(E.)* Salmon, P. A.; Reedyk, L. (Dep. Surg., Univ. Alberta, Edmonton, Canada). *Surg. Gynecol. Obstet.* 141(1):75-84, 1975.

The natural course of fatty metamorphosis of the liver was studied in 106 patients who underwent end-on-jejunoileal bypass between 1967 and 1970. Wedge or percutaneous needle liver biopsies were performed on all patients at the time of surgery and at various intervals thereafter. The biopsy material was examined for evidence of fatty metamorphosis and cirrhosis, and liver function tests were performed within a few hr of each biopsy. Two-thirds of all preoperative patients had some degree of fatty metamorphosis of the liver and at least 8-10% had marked steatosis prior to the bypass procedure. Marked fatty metamorphosis was most common in the massively obese patients, while the incidence of moderate to minimal fatty infiltration was highest in the less obese patients; there was, however, no strict correlation between degree of fatty infiltration and obesity. After surgery, 95% of the patients showed moderate to severe fatty metamorphosis within the first 300 days. Subsequently, the incidence of fatty infiltration rapidly decreased, so that by 1500-2000 days postsurgery, the incidence of severe steatosis had returned to preoperative levels; only those patients with marked postoperative involvement and complications late in the postoperative course had a severe degree of fatty metamorphosis after 1000 days. The liver function tests were of no value in detecting quiescent cirrhosis or minimal to moderate degrees of fatty metamorphosis, and showed only inconsistent changes in those patients with severe steatosis. Cirrhosis occurred in one patient after the liver was completely cleared of fat and was present to a degree in another patient at the time of bypass. Mononuclear cell infiltration of the portal tracts was found in about 50% of the preoperative biopsies, but did not correlate well with the incidence of hepatic steatosis. Because severe postoperative fatty infiltration in patients with preoperatively normal or minimally infiltrated livers occurred during the period of rapid weight loss, it is suggested that the extensive mobilization of depot stores of fat to fulfill the caloric requirements of the patient results in the accumulation of triglyceride in the liver. Steatosis may be further aggravated by the reduction in protein absorption and concomitant reduction in the formation of low-density lipoproteins in the liver.

6112 LIVER FAILURE IN THE POSTOPERATIVE PATIENT: THE ROLE OF SEPSIS AND IMMUNOLOGIC DEFICIENCY. *(E.)* Norton, L.; Moore, G.; Eiseman, B. (Univ. Colorado Med. Cent., Denver). *Surgery* 78(1): 6-13, 1975.

The cellular immune response was studied in 20 of 73 patients who developed liver failure and coma preoperatively. Quantitation of the cellular immune response in these patients, most of whom were alcoholic, included a differential leukocyte count, reduction of nitroblue tetrazolium by the blood neutrophils, the lymphocyte phytohemagglutinin (PHA) response, the ratio of T:B lymphocytes, serum immunoglobulin (Ig) A, G, and M levels, serum zinc concentration, lymphocyte sensitization to a skin test antigen, and skin reactions to intradermal tuberculin, mumps, and *Candida albicans* antigen. Among the 73 original patients, bacterial sepsis, generally of i.p. origin, was a major contributing factor in precipitating hepatic failure in 27; the mortality rate in this group was 48%. Massive blood loss and prolonged hypotension precipitated coma in 14 patients, of whom 10 died, bleeding from esophageal varices precipitated liver failure in 25 patients, 23 of whom died. Four patients had serum hepatitis and two died, and liver failure was attributed to the toxic effects of anesthesia in three patients, two of whom died. The cellular immune response in the 20 cirrhotic patients showed a reduced leukocyte count, a significant reduction in the lymphocyte PHA response, T lymphocyte count, and serum zinc concentration, and significant increases in serum IgA, IgG, and IgM. The percentage of cirrhotic patients reacting positively to intradermal tuberculin, mumps, and *Candida albicans* antigen was also increased over control levels. The results suggest the presence of a depressed cellular immune response in cirrhotic patients; thus, once such patients become septic, they are at double risk since they cannot mount a proper immunologic response. An aggressive attitude toward the elimination of infection is justified, therefore, as is re-exploration in any postoperative or postinjury patient who has any possibility of having undrained i.p. sepsis.

6113 SIGNIFICANCE OF ELEVATED LIVER ALKALINE PHOSPHATASE IN SERUM. *(E.)* Brensilver, H. L.; Kaplan, M. M. (New England Med. Cent. Hosp., Boston, Mass.). *Gastroenterology* 68(6):1556-1562, 1975.

To verify the hepatic origin of the band L isoenzyme, polyacrylamide gel electrophoresis was used to fractionate the serum alkaline phosphatase in 317 patients in whom the cause of the alkaline phosphatase elevation was not apparent or in whom the elevation appeared out of proportion to the extent of the disease present. In 87 patients with increased L band activity who did not have clinically apparent liver disease, liver biopsies and liver function tests were also performed. Of the original 317 sera, the alkaline phosphatase elevation was due to band L in 253. These 253 patients included 166 with hepatic disorders generally associated with such an elevation; the mean alkaline phosphatase in this group was 19.6 Bodansky U, compared with 8.8 in the 87 patients with increased L band activity in whom there was no apparent liver disease. In 19 of the latter 87 cases, liver disease was further excluded by liver biopsy, liver function tests, and/or laparotomy. The 87 cases also included 19 with acute coronary vascular disease or congestive heart failure in whom unrecognized passive congestion of the liver may have contributed to the alkaline phosphatase elevation. None of the other patients, including 24 with Hodgkin's disease and nine with tumors, had recognizable liver disease. In light of these findings, studies were undertaken to confirm the hepatic origin of band L. Band L and alkaline phosphatase extracted from human liver migrated together on polyacrylamide gels before and after digestion with *Vibrio cholerae* neuraminidase and they had identical pH optima, sedimentation coefficients, Michaelis constants, and rates of inactivation at 55.5 C. However, they had different rates of inactivation in 3 M urea. Overall, the data indicate that band L is of liver origin and that elevation of the hepatic alkaline phosphatase isoenzyme may be a nonspecific finding in certain patients.

6114 THE RELATIONSHIP OF RED CELL MEMBRANE LIPID CONTENT TO RED CELL MORPHOLOGY AND SURVIVAL IN PATIENTS WITH LIVER DISEASE. *(E.)* Powell, L. W.; Halliday, J. W.; Knowles, B. R. (R. Brisbane Hosp., Queensland, Australia). *Aust. N. Z. J. Med.* 5(2): 101-107, 1975.

The relation between RBC membrane lipid content and RBC morphology and survival was studied in 15 patients with hepatic cirrhosis and seven patients with cholestatic jaundice. RBC morphology was also studied in 56 additional patients with hepatic cirrhosis to determine the prevalence of deformed RBC in this disease. Serum lecithin:cholesterol acyltransferase (LCAT) activity and RBC lipids were determined in the original 22 cirrhotic and jaundiced patients and in seven healthy volunteers. RBC morphology was studied in all liver disease patients using air dried smears, wet preparations, and scanning electron microscopy of the peripheral blood. RBC survival was measured by the radioactive chromium technique. Both RBC cholesterol and RBC phospholipid were significantly elevated over control values in the patients with liver disease, the type of disease having no significant correlation with the degree of elevation. In two patients with significant numbers of "spur" poikilocytes in the peripheral blood, RBC cholesterol was significantly increased but RBC phospholipid content was normal. The serum cholesterol levels did not correlate significantly with the RBC lipid levels. Serum LCAT activity was reduced in liver disease, the level of enzyme activity correlating significantly with the serum total bilirubin; it did not correlate significantly with RBC cholesterol or phospholipid values or serum cholesterol content. Peripheral blood smears from the liver disease patients regularly showed macrocytes, target cells, and some poikilocytes, but the number of deformed RBC did not correlate with RBC lipid content or RBC survival. Of the additional 56 hepatic cirrhosis patients in whom morphology was studied, distorted RBC were found in only two. RBC survival was reduced in most patients, but the degree of hemolysis did not correlate significantly with RBC lipid, the presence or degree of splenomegaly, or serum iron, folate, or vitamin B_{12} concentrations. Marked hemolysis was, however, correlated with a large number of spur poikilocytes. The results indicate that only in patients with spur-cell anemia do the morphologic alterations lead to the premature removal of cells from the circulation.

6115 HEPATOCELLULAR CARCINOMA AND A VARIANT ALKALINE PHOSPHATASE. *(E.)* Higashino, K.; Ohtani, R.; Kudo, S.; Hashinotsume, M.; Hada, T.; Kang, K. Y.; Ohkochi, T.; Takahashi, Y.; Yamamura, Y. (Osaka Univ. Sch. Med., Japan). *Ann. Intern. Med.* 83(1):74-78, 1975.

The clinical, laboratory, and pathologic findings in patients with a variant alkaline phosphatase are reported, and the usefulness of this enzyme in the diagnosis of hepatocellular carcinoma is discussed. Serum samples were obtained from 100 control subjects, 13 patients with primary hepatoma, and 117 patients with other liver and extrahepatic diseases; liver and tumor tissues were obtained at autopsy from 13 patients with hepatoma and 94 patients with other diseases. Alkaline phosphatase was extracted from these tissues, fractionated, and subjected to polyacrylamide gel electrophoresis. Screening for serum alpha-fetoprotein was done by a micro double diffusion method. Four of the 13 primary hepatoma patients had the variant serum alkaline phosphatase, which resembles the placental D-variant but differs from it in electrophoretic mobility, pH optimum, heat stability, and inhibition by phosphate. The appearance of the variant enzyme was independent of serum alkaline phosphatase activity and was not found in the sera of patients with diseases other than hepatocellular carcinoma. Alpha-fetoprotein was found in the sera of 10 of the 13 primary hepatoma patients, the occurrence of the deviant serum enzyme being independent of the alpha-fetoprotein concentration and the appearance of the Regan or Nagao isoenzymes. The tumor tissues of three patients with the variant serum enzyme were examined and all were found to contain the enzyme in question. Since all of the patients in whom the variant alkaline phosphatase was present had a massive type of hepatocellular carcinoma with grade III differentiation by Edmondson's classification, the detection of this enzyme in the serum may be of value in confirming a diagnosis of hepatoma.

6116 LIVER MORPHOLOGY AND LIVER FUNCTION BEFORE AND AFTER INTESTINAL SHUNT OPERATION FOR OBESITY.

(E.) Dano, P.; Nielsen, O. V.; Petri, M.; Jorgensen, B. (Rigshosp., Copenhagen, Denmark). *Scand. J. Gastroenterol.* 10(4):409-416, 1975.

The influence of obesity and intestinal shunt operation on liver function and morphology was studied in 49 patients. Liver biopsy and liver function tests were performed in 17 patients before and 14 months after the bypass operation. In another 20 patients, liver biopsy was performed postoperatively only, and in 13 patients preoperatively only. Three types of operations were performed: in type I, 36 cm of proximal jejunum was anastomosed end-to-side to 12 cm of terminal ileum; in type II, 24 cm of proximal jejunum was anastomosed to 24 cm of terminal ileum; and in type III, 12 cm of proximal jejunum was anastomosed to 36 cm of terminal ileum. Weight loss after the operation was most pronounced during the first 6 months and the degree of loss did not vary significantly according to the type of operation. In 29 patients with liver biopsy before surgery, steatosis was present in 25. In the 17 patients examined 14 months after surgery, the degree of hepatic steatosis was increased in seven, decreased in eight, and unchanged in two. In eight patients, a further biopsy 15 months later showed decreased steatosis in five and no alteration in three. There was no correlation between the rate of weight loss in the first 12 months and the change in hepatic steatosis. In the 20 patients examined postoperatively only, all had hepatic steatosis; in 10 patients examined several months later, hepatic steatosis was decreased in five and unchanged in five. No patient developed cirrhosis during the time of observation, although one patient each in the preoperative and postoperative only groups had cirrhosis. Within the first postoperative yr, there was a significant increase in the serum alanine-aminotransferase levels and a minor increase in alkaline phosphatases and BSP; these changes did not correlate with the rate of weight loss or degree of steatosis. The incidence of gallbladder disease was 15% preoperatively and two additional patients were cholecystectomized postoperatively. The results indicate that both serial biopsies and quantitative measurements of hepatic lipid are necessary when further information on the influence of the bypass operation on the liver is desired. The intestinal shunt operation is still recommended in selected cases of obesity.

6117 α-FETOPROTEIN IN NONNEOPLASTIC HEPATIC DISORDERS.

(E.) Bloomer, J. R.; Waldmann, T. A.; McIntire, K. R.; Klatskin, G. (Yale Univ. Sch. Med., New Haven, Conn.) *JAMA* 233(1):38-41, 1975.

To define the specificity of the radioimmunoassay for serum α-fetoprotein as a diagnostic test for hepatoma, serum α-fetoprotein levels were measured by radioimmunoassay in 473 patients with biopsy-proven nonneoplastic disorders. The patients ranged in age from 3 yr to 80 yr; their diseases included viral hepatitis, inactive postnecrotic cirrhosis, chronic active hepatitis, drug-induced hepatitis, primary biliary cirrhosis, alcoholic liver disease, extrahepatic biliary disease, obstructive jaundice, and other miscellaneous hepatic disorders. α-Fetoprotein levels were also measured in 75 patients with proved hepatocellular carcinoma, 350 patients with nonhepatic nonneoplastic disease, and 130 healthy volunteers. Among the patients with nonneoplastic hepatic disorders, 22% had α-fetoprotein values greater than 40 ng/ml, levels exceeding 40 ng/ml being found in 30% of the patients with various types of hepatitis, and in 0-15% of those with other diseases. None of the healthy controls and only one of the patients with nonhepatic benign diseases had an α-fetoprotein value over 40 ng/ml. Among the 75 hepatoma patients, serum α-fetoprotein levels exceeded 40 ng/ml in 69% and exceeded 3000 ng/ml in 48%. The results indicate that radioimmunoassay may, because of its sensitivity, become the method of choice for measuring α-fetoprotein levels in patients with primary hepatoma, although some specificity for the diagnosis of hepatoma will be lost. The occurrence of elevated serum α-fetoprotein levels in several other nonneoplastic hepatic disorders may reflect hepatic regeneration.

6118 DIAGNOSTIC VALUE OF SERUM BILE ACIDS.

(Ger.) Schwarz, H. P.; Paumgartner, G.; Preisig, R. (Inst. Clin. Pharmacol., Univ. Bern, Switzerland). *Schweiz. Med. Wochenschr.* 105(17):533-535, 1975.

Fasting serum bile acids, serum bilirubin, SGOT, alkaline phosphatase, the galactose excretion test, and BSP retention and clearance tests were performed on 60 normal controls, 14 patients with Gilbert's syndrome, four with Dubin-Johnson syndrome, and 48 with a variety of liver diseases. Bile acids were extracted with Amberlite XAD-2, incubated with 3α-hydroxysteroid dehydrogenase, and measured fluorimetrically. In controls, serum bile acid levels ranged from 1.6 to 9.2 μM/liter (means 6.1 ± 1.7 μM/liter for males and 5.9 ± 1.7 μM/liter for females). All 14 patients with Gilbert's syndrome and two of the four with Dubin-Johnson syndrome had values within the normal range; the two other patients with Dubin-Johnson had slightly elevated levels (10.5 and 10.6 μM/liter, resp.). With the exception of two patients with fatty liver and one with cryptogenic cirrhosis, patients with all other liver diseases (94%) had increased serum bile acid levels. However, a differential diagnosis could not be established on the extent of this increase. BSP retention gave abnormal results in 96%, BSP clearance in 90%, SGOT in 88%, galactose excretion in 65%, alkaline phosphatase in 60%, and serum bilirubin in 40%. Significant correlations were found between serum bile acid levels and BSP retention, the BSP clearance constant k_1, and serum total bilirubin values. However, large discrepancies were noted in some cases: 27 of the 45 patients with increased bile acid values had normal serum bilirubin levels. When serum bile acid determinations were repeated 2 hr after a standard breakfast (egg, bread and butter, coffee), significant postprandial increases occurred in all eight patients with cirrhosis and all 10 controls tested. However, bile acid concentrations of more than 10 μM/liter were never observed in controls. This relatively simple method for determining serum bile acids appears to be a very sensitive method for diagnosing liver disease. In patients with normal or borderline values, determinations should be repeated 2 hr after a standard breakfast. Since serum bile acid values in three patients with cirrhosis increased significantly after portacaval shunt surgery and excretory liver function, measured with the BSP transport maximum, remained the same, the increased bile acid concentrations found in patients with liver disease appear to be due both to impaired liver cell function and porto-systemic shunts.

6119 CRITERIA FOR THE ACTIVITY OF PATHOLOGICAL CONNECTIVE TISSUE PROLIFERATION IN CHRONIC LIVER DISEASE. *(Ger.)* Grasedyck, K.; Helle, M.; Lindner, J.; Langness, V. (1st Med. Clin., Univ. Hamburg, Germany). *Verh. Dtsch. Ges. Inn. Med.* 80: 503-506, 1974.

Total collagen contents, expressed as hydroxyproline, and collagen synthesis, using prolyl hydroxylase activity as the criterion, were measured in the livers of 10 cadavers. Collagen was also separated into four fractions on the basis of solubility in neutral salt and acid solutions. The collagen content increased proportionally with the extent of fibrosis or cirrhosis, but no relation was observed between the extent of fibrosis and the distribution pattern for individual collagen fractions. However, total collagen values obtained on fat-free dry tissue agreed well with values for the collagen fractions. Measurements of collagen in serial sections from cadaver liver showed that scattering amounted to 10-20%. With the technique employed, it is possible to determine total collagen in tissue samples as small as 20-30 mg wet weight or 5-8 mg dry weight. Hydroxyproline levels were 10-20 μg in normal livers and more than 100 μg in pathological livers. Preliminary studies demonstrated that the use of prolyl hydroxylase activity as a criterion for collagen synthesis gave significantly different values for patients with cirrhosis and those with normal livers. Although these findings give no information on correlations between the extent of newly formed connective tissue or the prognosis, insight into fibrosis can be obtained if the total collagen content and prolyl hydroxylase activity are determined in needle biopsies.

6120 CYTOCHROME P-450-DEPENDENT 6α-HYDROXYLATION OF TAUROLITHOCHOLIC ACID IN MAN. *(Ger.)* Czygan, P.; Greim, H.; Trultsch, D. (Med. Clin., Univ. Heidelberg, Germany). *Verh. Dtsch. Ges. Inn. Med.* 80:445-447, 1974.

To demonstrate that cytochrome P450 takes part in 6α-hydroxylation of taurolithocholic acid in normal human liver microsomes, the reaction kinetics, CO inhibition, and the reversibility of CO inhibition by light at 450 nm were investigated. The 6α-hydroxylation of taurolithocholic acid followed Michaelis-Menten kinetics up to a substrate concentration of approximately 0.3 mM. Inhibition occurred at higher concentrations due to the detergent action of taurolithocholic acid. The K_M was 0.21 mM, a value that agrees with those found in other cytochrome P450-dependent reactions, and the maximum reaction rate was 0.79 nM/min/mg microsomal protein. When this reaction was carried out in the presence of 2-48% CO and 4% O_2 for five min at 30 C, inhibition of 6α-hydroxylation increased with increasing CO concentrations. A Warburg distribution constant, K, of 1.8 was obtained at 50% inhibition, a value similar to those reported for other cytochrome P450-dependent reactions. CO-induced inhibition of 6α-hydroxylation was reversed most rapidly when the incubation mixture was exposed to monochromatic light having a wavelength of 450 nm. These findings can be regarded as definite proof that cytochrome P450 takes part in 6α-hydroxylation of taurolithocholic acid. This may be the first demonstrated cytochrome P450-dependent reaction in bile acid metabolism in man. This reaction might be useful in explaining the etiology of intrahepatic cholestasis since drugs which cause this condition and are metabolized by the cytochrome P450-enzyme system would interfere with hydroxylation of taurolithocholic acid. However, it is not known whether this hepatotoxic bile acid would contribute to intrahepatic cholestasis or whether it would only result in potentiation.

6121 HISTOGENETIC STAGES BETWEEN POLYCYSTIC LIVER AND "CONGENITAL HEPATIC FIBROSIS". STUDY OF TWO CASES IN ADULTS. *(It.)* Tomasino, R. M.; Genova, G.; Messina, L. (Inst. Anat. Pathol. Histol., Univ. Palermo, Italy). *Arch. De Vecchi Anat. Patol.* 59(2):261-292, 1973.

Case reports are presented for a 39-yr-old woman with polycystic liver associated with polycystic kidney and a 40-yr-old woman with "congenital fibrosis of the liver." From histological findings it is concluded that these two conditions are actually early and late forms, resp., of the same disease. Laparoscopy of the first patient revealed many cystic protuberances of a greyish-white color, which varied in size from a hazel nut to a hen's egg. A needle biopsy showed dilatation and congestion of the sinusoids; their lumens were filled with many blood cells. Inflammatory infiltrates were present in the periportal region and in the parenchyma; these were associated with diffuse fatty liver and signs of regeneration. The diameters of dilated ductal formations, found in the parenchyma and areas distant from the portal triad, were consistent with those of intralobular bile ducts; these were covered with cylindrical epithelium in which the nuclei were shifted toward the base of the cell and the cytoplasm stained with periodic acid-Schiff's reagent. These structures, which occurred singly or in groups of two or three, consisted only of epithelial covering resting on a very thin fibrous wall surrounded by a layer of hepatocytes; small quantities of bile were present in their cavities. The second patient had a five-yr history of splenomegaly associated with gastrointestinal discomfort. At laparoscopy the spleen and liver were increased in size; the liver was hard, greyish, and "precirrhotic" in appearance. Histological examination of a large fragment of the liver showed thick bands of scarring which separated the parenchyma and surrounded roundish islands of the muralium simplex. In some areas hepatocytes contained lipofuscin pigment. Proliferation of thick bands of connective tissue surrounding the bile ducts was found in all areas examined. As in the first case, proliferation of the intralobular bile ducts was detected; it was not associated with either inflammatory changes or parenchymal necrosis.

6122 A CASE OF ENCAPSULATING PERIHEPATITIS TREATED BY PORTACAVAL ANASTOMOSIS AND HEPATIC DECORTICATION. *(Fr.)* Chevrel, J. P.; Gueraud, J. P. (Franco-Musulman Hosp., Bobigny, France). *Chirurgie* 100(11):806-815, 1974.

A 44-yr-old woman, hospitalized for recurrent hematemesis, had alcoholic cirrhosis associated with portal hypertension and esophageal varices. She had a history of tuberculosis and had undergone nephrectomy on the left 11 yr previously. Clinical examination showed hepatosplenomegaly, conjunctival subicterus, ascites, and Cruveilhier-Baumgarten syndrome. When the peritoneum was opened for omphalography, the liver did not appear nodular and cirrhotic, but resembled the icing of a cake. Although the patient later stopped drinking and gained weight, her liver became more enlarged and she was readmitted to undergo hepatic decortication in association with an end-to-side portacaval shunt. A biopsy of the liver taken at this time confirmed the existence of micronodular cirrhosis associated with moderate steatosis and Curschmann's encapsulating perihepatitis. The patient's recovery was uneventful and one year after surgery her condition has stabilized: the liver is normal in size, liver function tests have improved considerably, and there has been no recurrence of hematemesis, ascites, or edema of the lower extremities; portacaval encephalopathy has not developed, but the patient is currently suffering from polyneuritis.

6123 THE ISOLATION AND CHARACTERIZATION OF PLASMA LIPASE OF HEPATIC ORIGIN: PRELIMINARY CLINICAL FINDINGS IN PATIENTS WITH VARIOUS LIVER DISEASES. *(Ger.)* Klose, G.; Greten, H. (Med. Clin., Heidelberg Univ., Germany). *Verh. Dtsch. Ges. Inn. Med.* 80:1272-1274, 1974.

The activities of a lipase of hepatic origin, which hydrolyzes triglycerides, and of a lipoprotein lipase from fatty tissue were determined in heparinized blood taken from 13 patients with a variety of liver diseases (acute and chronic hepatitis, fatty liver and cirrhosis) and from eight normal controls. Plasma was extracted successively with acetone, heptane, ethanol-ether, and ether at 4 C to remove lipids which normally form a complex with heparin. Proteins were dissolved in barbital buffer (pH 7.4) and incubated with ^{14}C-labeled triolein to which albumin and detergents had been added for 30 min at 27 C. The ^{14}C-labeled free fatty acids were then isolated by passage through an ion-exchange resin and their activity was determined. More than 50 μM/5 ml/hr of free fatty acids were found in total postheparin plasma from seven of the eight controls, while less than 40 μM/5 ml/hr were found in serum from 12 of the 13 patients with liver disease. Calculation of the ratios between triglyceride lipase of hepatic origin and lipoprotein lipase from fatty tissue showed values of less than 2:1 for most of the patients and values as high as 10:1 in the control group. It is suggested that increased triglyceride concentrations in the blood of patients with liver disease are due, at least in part, to a decrease in plasma triglyceride lipase synthesized in the liver.

6124 BILE ACIDS IN THE LIVER AND SERUM IN VARIOUS LIVER DISEASES. *(Ger.)* Greim, H.; Czygan, P. (Toxicol. Inst., Univ. Tubingen, Germany). *Verh. Dtsch. Ges. Inn. Med.* 80:443-445, 1974.

So that comparisons could be made between serum and liver bile acids, a technique was developed for determining individual bile acids in needle liver biopsies weighing 5 to 15 mg. Liver was solubilized in 3.4 N KOH which was then neutralized with HCl. Glycine and taurine conjugates were hydrolyzed with 50 μl of cholylglycyl hydrolase in a solution containing 3.5 ml of buffer mixture at pH 5.6 (0.1 M acetate buffer and 0.01 M each of β-mercaptoethanol and EDTA-Na_2). After ether extraction, thin-layer chromatography with a hexane-ethyl acetate (9:1) eluant, and methylation, bile acids were determined by gas-liquid chromatography as their trifluoroacetyl or trimethylsilyl derivatives. Serum bile acids were determined by hydrolyzing 0.5 ml of serum with 3 ml of buffer mixture and enzyme and proceeding as above. Cholic, deoxycholic and chenodeoxycholic acid contents of the liver were compared with their serum concentrations in three patients with liver disease (chronic aggressive hepatitis, sclerosing cholangitis, and cholestasis caused by testosterone) and in six patients with no evidence of liver disease. The ratio of serum to liver bile acid varied between 1:2 and 1:30 so that serum bile acid concentrations give no information about their content in the liver. In part, this can be attributed to the method used which also detects extracellular bile acids. However, with the exception of the patient with chronic aggressive hepatitis, the distribution pattern of bile acids was almost identical in liver and serum. This finding was confirmed in three patients with primary biliary cirrhosis and increased cholic acid levels and in three patients with chronic persistent hepatitis and relatively small increases in bile acid concentrations in both compartments. Therefore, determination of individual bile acids in the serum does give information about the bile acid distribution pattern in the liver.

6125 HEPATIC RETICULOENDOTHELIAL HOST DEFENSE FAILURE FOLLOWING SURGICAL TRAUMA. *(E.)* Scovill, W. A.; Saba, T. M. (Albany Med. Coll., N.Y.). *Arch. Surg.* 110(8):954-959, 1975.

The potential pituitary adrenal influences on postoperative reticuloendothelial function was evaluated in male dogs pretreated with dexamethasone sodium phosphate (3 mg i.m. twice a day for 3 days, with the last dose increased to 6 mg). The operative procedure consisted of right hemicolectomy. The reticuloendothelial function was evaluated by a colloid clearance technique and the plasma opsonic activity was determined before and after surgical trauma by an *in vitro* bioassay. Three hr after surgery significant phagocytic depression was evident in untreated animals by an almost 50% decrease in the global phagocytic index K (vascular clearance of the i.v. injected colloid). There was a 30% decline in opsonic activity. Both the global phagocytic index K and the plasma opsonic activity of control, dexamethasone-pretreated animals were not significantly different than control nontreated animals. In dexamethasone-pretreated dogs, the K value of 0.79 was not significantly changed from control nontraumatized animals. Although opsonic activity declined in the dexamethasone-treated animals, values were not significantly different from control. Cortisone acetate or ACTH over a wide dosage range manifested no depressing effect on *in vitro* phagocytosis. The manipulation of pituitary adrenal function appears to have a substantial postoperative influence on hepatic macrophage function. The precise mechanism of this regulatory influence is unknown but it would appear to be of a hemestatic or permissive nature at the cellular level.

6126 QUANTITATIVE DETERMINATION OF THE ABNORMAL LIPOPROTEIN OF CHOLESTASIS, LP-X, IN LIVER DISEASE. *(E.)* Ritland, S. (Univ. Hosp., Oslo, Norway). *Scand. J. Gastroenterol.* 15(11):5-15, 1975.

Quantitative determination of an abnormal lipoprotein, lipoprotein-X (LP-X) was performed in 15 patients with acute hepatitis, seven with toxic hepatitis, 10 with primary biliary cirrhosis, one with other cirrhosis, two with cholestasis of pregnancy, 10 with sclerosing cholangitis, six with cholecocholithiasis, 30 with extrahepatic biliary obstruction by tumors, and 17 patients with an uncertain diagnosis. Blood samples were drawn in the fasting state, and determinations of LP-X, free and total cholesterol, and α-lipoprotein, serum bilirubin, alkaline phosphatases, albumin, and SGOT were made. Great variations in the plasma LP-X concentration were demonstrated in the 45 patients with intrahepatic cholestasis and in the 36 patients with extrahepatic cholestasis, although the median LP-X concentrations were significantly higher in the former group (158 mg/100 ml) than in the latter group (25 mg/100 ml). However, the highest LP-X level in the intrahepatic cholestasis group (252 mg/100 ml) was exceeded by 42% of the extrahepatic biliary obstruction patients, 33% of whom had plasma LP-X levels greater than 400 mg/100 ml. The plasma LP-X concentration was significantly correlated with free cholesterol, plasma alkaline phosphatases, and serum bilirubin levels, but seemed superior to the latter two parameters in differentiating between intrahepatic and extrahepatic cholestasis. Plasma LP-X concentrations exceeding 400 mg/100 ml are highly indicative of extrahepatic biliary obstruction.

6127 STEROID HORMONES AND THEIR BINDING IN PLASMA OF MALE PATIENTS WITH FATTY LIVER, CHRONIC HEPATITIS AND LIVER CIRRHOSIS. *(E.)* Kley, H. K.; Nieschlag, E.; Wiegelmann, W.; Solbach, H. G.; Kruskemper, H. L. (Med. Univ. Clin., Dusseldorf, Germany). *Acta Endrocrinol. (Kbh.)* 79(2):275-285, 1975.

Plasma estrone (E_1), estradiol (E_2), testosterone (T), cortisol (F), and luteinizing hormone (LH) levels were studied in 10 male patients with fatty liver, six male patients with chronic hepatitis, 15 male patients with cirrhosis of the liver, 25 healthy young (19-40 yr) male subjects, and 25 healthy older males (61-89 yr); the percentage of bound T, E_1, E_2, and F in the plasma was also measured. The plasma E_1, E_2, T, and LH concentrations were measured radioimmunologically using specific antisera, plasma F was determined by the competitive protein binding method, and the percentage of binding of E_1, E_2, T, and F was determined by equilibrium dialysis. The testes were normal in most of the patients with fatty liver and chronic hepatitis, but were small and soft in nine of the cirrhotic patients. Four fatty liver patients, 2 chronic hepatitis patients, and 12 cirrhotic patients complained of reduced potency or impotence, and gynecomastia was found in 10 of the cirrhotic patients. The plasma T concentrations were low normal in the fatty liver patients, reduced below normal levels in two hepatitis patients, and significantly reduced in the cirrhotic patients. The E_2 concentrations were normal in the fatty liver and chronic hepatitis patients and only slightly increased in the cirrhotic patients. The E_1 concentrations were also significantly increased in the cirrhotic patients and the plasma LH levels were increased by 50% over normal values in the hepatitis and cirrhosis patients. The F levels showed no dependence on age or hepatic disease. The percentage of bound T and E_2, but not that of E_1 or F, was also increased in the cirrhosis and hepatitis patients. In comparison with the young controls, the E_2/T ratio was moderately increased in the fatty liver patients, more markedly increased in the hepatitis patients, and greatly increased in the cirrhotic patients; these increases were even more marked in the E_1/T ratio. It is suggested that the combination of elevated E_1 and E_2 and reduced T may be responsible for the gynecomastia and hypogonadism in chronic liver diseases. Furthermore, altered liver function may be responsible for alterations in steroid plasma concentrations and their binding to plasma proteins in both older men and liver disease patients.

6128 BILE ALCOHOL METABOLISM IN MAN: CONVERSION OF 5β-CHOLESTANE-3α,7α,12α,25-TETROL TO CHOLIC ACID. *(E.)* Salen, G.; Shefer, S.; Setoguchi, T.; Mosbach, E. H. (VA Hosp., East Orange, N. J.). *J. Clin. Invest.* 56(1):226-231, 1975.

To study the role of C_{25}-hydroxy bile alcohols as precursors of cholic acid, (G-^{3}H)5β-cholestane-3α,7α,12α,-25-tetrol was administered i.v. to two patients with cerebrotendinous xanthomatosis (CTX) and two normal individuals. One day after pulse labeling, radioactivity was present in the cholic acid isolated from the bile and feces of the CTX subjects and the bile of the normal controls. In the two controls, the specific activity decay curves of (G-^{3}H)cholic acid were exponential, and no traces of (G-^{3}H)5β-cholestane-3α,7α,12α,25-tetrol were detected. In contrast, appreciable quantities of labeled 5β-cholestane-3α,7α,12α,25-tetrol were present in the bile and feces of the CTX patients. The specific activity *versus* time curves of fecal (G-^{3}H)5β-cholestane-3α,7α,12α,25-tetrol and (G-^{3}H)cholic acid showed a precursor-product relation in both groups of subjects. Although these results suggest that 5β-cholestane-3α,7α,12α,25-tetrol may be a precursor of cholic acid in man, the possibility that C_{26}-hydroxy intermediates represent the normal pathway cannot be excluded. The results also support the hypothesis that the genetic abnormality in CTX results in impaired bile acid synthesis, specifically, incomplete degradation of the cholesterol side chain.

6129 SELECTIVE LIGATION OF THE HEPATIC ARTERY FOR TRAUMA OF THE LIVER. *(E.)* Aaron, S.; Fulton, R. L.; Mays, E. T. (Univ. Louisville Sch. Med., Ky.). *Surg. Gynecol. Obstet.* 141(2):187-189, 1975.

The role of ligation of the hepatic artery in obtaining hepatic hemostasis is described in 60 patients over a 12-yr period. The right ramus was ligated in 36 patients, the left ramus in 15 patients, and the common hepatic artery in nine patients. In 55 patients, the artery was ligated on the day of injury at the time of initial laparotomy. Hemostasis and improved hemodynamic status were immediate and permanent in 49 patients. Six patients died in the operating room or immediately after laparotomy from head injury or uncontrolled hemorrhage from nonhepatic sites. Five patients required multiple laparotomies, and hemostasis was achieved in all cases after hepatic artery ligation. In three patients who had hepatic resection as the primary method of treating the hepatic wound, hemorrhage from the liver was profuse following resection. This postresection bleeding was controlled by hepatic artery ligation, and all patients survived. In a fourth patient, who had a severed left lateral segment, left hepatic artery ligation was used in conjunction with resection to successfully control hemorrhage. Seventeen patients died, including two with hemorrhage from perihepatic sites. The most common cause of death was sepsis, primarily subphrenic and pulmonary; six patients died from events unrelated to liver trauma. Hepatic insufficiency did not occur in survivors. It is concluded that ligation of the hepatic artery is an effective method of achieving hepatic hemostasis; it is simple, rapid, and universally applicable with predictable sequelae.

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

6210 SLOW INFUSION CHOLANGIOGRAPHY IN PATIENTS WITH JAUNDICE. *(Ger.)* Fuchs, W. A.; Preisig, R. (Inselspital, Bern, Switzerland). *Fortschr. Geb. Roentgenstr. Nuklearmed.* 122(2):148-151, 1975.

A solution of 40 ml (20 g) ioglycamide in 500 ml physiological saline was infused dropwise over a 10 hr period, i.e. at a rate of about 35 mg/min, in 30 fasting patients (19 men and 11 women, aged 20-77 yr) with jaundice caused by a variety of hepatobiliary diseases. All patients had serum bilirubin levels of 4 mg/100 ml or more (1.4-13.6 mg/100 ml), and all were suspected of having extrahepatic biliary obstructions. X-rays were taken with the patients in a prone position, using 75 kilovolts or less, before and 15 min after p.o. administration of 1 g lecithin suspended in 25 ml of an emulsion of egg yolk and glycerol. Tomography was routinely used for better visualization of the gallbladder and bile ducts which, in many cases, filled only slightly. The diagnosis was confirmed by surgical exploration in 18 cases, by histological findings in association with the clinical course in 11 cases, and at autopsy in one case. Slow infusion cholangiography made it possible to establish a correct radiological diagnosis in 11 of 30 patients (38%). While visualization of the extrahepatic bile ducts was good enough to establish a diagnosis in only 2 of 15 patients with extrahepatic biliary obstructions (13%), a radiological diagnosis was made in 9 of 15 patients with parenchymal liver disease (60%).

6211 LONG-TERM PROGNOSIS IN INTRAHEPATIC BILIARY ATRESIA AND IN THE SO-CALLED NEONATAL HEPATITIS. *(Ger.)* Osswald, P.; Gathmann, H.; Muller, G. (Child. Clin., Univ. Tubingen, Germany). *Monatschr. Kinderheilkd.* 123(5):445-447, 1975.

Follow-ups were performed on 20 infants with histologically confirmed neonatal hepatitis and on nine with hypoplasia of the intrahepatic bile ducts.

While rapid regression of the symptoms of neonatal hepatitis was a favorable sign, laboratory examinations performed in initial stages of the disease were of little value in establishing a prognosis. Of the 20 infants (16 boys and four girls) with neonatal hepatitis, nine showed histological evidence of giant cell transformation. In contrast to other reports in the literature, the symptoms and course of infants with giant cell transformation did not differ appreciably from those in the remaining 11 patients. Jaundice developed by age 2 weeks in 2/3 of these patients and, with one exception, maximum total bilirubin values ranged from 4.8 to 18.4 mg/100 ml. In six cases, neonatal hepatitis was associated with other diseases (toxoplasmosis, rubella, hepatitis B, α_1-antitrypsin deficiency and clinically diagnosed Edward's syndrome). Liver damage accompanied by clotting disorders, ascites, edema and, in some cases, in combination with intercurrent infection was the cause of death in the nine patients who died before their first birthday. Two other children died of hepatic coma and esophageal varices, resp., before 4 yr of age. Of these 20 children, only five showed no clinical evidence of residual liver damage at an average age of 6 yr, although the initial stages of cirrhosis were diagnosed histologically during the first four months of life, at which time bilirubin levels and all other liver function tests had normalized. Hypoplasia of the intrahepatic bile ducts, diagnosed in nine infants by histological findings on wedge liver biopsies, followed a benign course in four children; bilirubin levels and other liver function tests normalized by age 3-5 months and no residual clinical symptoms were apparent at ages 1.5 to 8 yr. In the remaining five cases, chronic cholestasis, increased portal fibrosis, and proliferation of the intralobular bile ducts developed along with a secondary disorder in lipid metabolism. The latter was accompanied by great increases in free cholesterol and phosphatide concentrations, a positive lipoprotein X test and significant increases in serum bile acid levels. Only 1/5 children developed

6212 USE OF OXYTOCIN AND INCIDENCE OF NEONATAL JAUNDICE.

(E.) Chalmers, I.; Campbell, H.; Turnbull, A. C. (London Sch. Hyg. Trop. Med., England). *Brit. Med. J.* 2(5963)116-118, 1975.

A retrospective controlled study using data from the Cardiff Births Survey was performed to examine a possible relation between oxytocin administration to induce or accelerate labor and the subsequent development of neonatal jaundice. The study group consisted of 10,591 infants, or 61% of the total live births between 1970-1972, and 95% of those discharged from 3-8 days after delivery. Of the 10,591 infants, 970 (9.2%) had a measured plasma bilirubin of at least 17 μM/liter. Of the 3326 born after oxytocin administration, 412 (12.4%) became jaundiced. Of the 5896 born after spontaneous labor, 476 (8.1%) were affected. Of the 1369 born after amniotomy, 82 (6.0%) developed jaundice. Of the 7265 infants in the latter two groups (no oxytocin), 558 (7.7%) became significantly jaundiced, so that the relative risk of jaundice in an infant born after oxytocin administration compared to the risk in other infants was 1.6. However, analysis by gestational age at delivery, birth weight, Apgar score, length of labor, sedative and analgesic therapy during labor, and suppression of lactation showed that the association between jaundice and oxytocin held within all these categories except among small immature infants who are at high risk of jaundice in any case. The apparent protection against jaundice conferred by amniotomy *versus* spontaneous labor reflected the low incidence of amniotomy at the early gestational age (36 and 37 weeks) which showed a high overall incidence of jaundice. Therefore, the infants born after spontaneous labor and those born after amniotomy were comparable with respect to the incidence of jaundice. These results support the hypothesis that the increasing resort to induction and acceleration of labor has been associated with a higher incidence of neonatal jaundice. It is suggested that this may not be the only enzyme system which is affected.

6213 MICROHETEROGENEITY OF COMPLEX GLYCOSIDES OF BILIRUBIN FROM HUMAN BILE.

(E.) Kuenzle, C. C. (Sch. Vet. Med., Univ. Zurich. Switzerland). *Experientia* 31(6):626-627, 1975.

A chromatographic system was developed to allow the preoperative separation of the aldobiouronide, hexuronosylhexuronide, and pseudoaldobiouronide conjugates of bilirubin on polyamide sheets. Bilirubin conjugates were isolated from human T-tube bile as their phenylazo derivatives, and the aldobiouronide, hexuronosylhexuronide, and pseudoaldobiouronide conjugates were obtained by column chromatography. These preparations were freed from contaminating celite, extracted with 1-butanol and dried. The residue was dissolved in methanol, streaked on polyamide sheets, and developed using a solvent system prepared from 4-methyl-2-penanone. Using this fractionation system, virtually identical chromatographic patterns were obtained for all three azo pigments. Three azo pigment subfractions were visualized in all three instances. Gross estimation of the subfractions gave an approximate intragroup ratio of 5:60:35. The system was not entirely satisfactory, however, in that the azo pigments of lowest mobility were incompletely separated from those of intermediate mobility; also, elution of the subfractions from the plates resulted in partial solubilization of the chromatographic support, thus contaminating the preparations with depolymerizing material. It is concluded that the aldobiouronic, hexuronosylhexuronic, and pseudoaldobiouronic acids involved in bilirubin conjugation are heterogeneous.

6214 FLUOROMETRIC DETERMINATION OF 'ALBUMIN-TITRATABLE BILIRUBIN' IN THE JAUNDICED NEONATE.

(Eng.) McCluskey, S. B.; Storey, G. N. B.; Brown, G. K.; More, D. G.; O'Sullivan, W. J. (Royal Prince Alfred Hosp., Camperdown, N.S.W. 2050, Australia). *Clin. Chem.* 21(11):1638-1643, 1975.

A fluorometric technique is presented for the determination of albumin-titratable bilirubin in the jaundiced neonate. Although bilirubin alone has very little fluorescence, considerable emission is observed in the presence of albumin under acid conditions. Blood samples were obtained from umbilical cord veins or by heelprick from newborn infants. Blood from normal healthy women volunteers was collected by venipuncture. Albumin in the plasma samples was determined by a modified bromcresol green method or, in the case of albumin solutions, by its absorption at 279 nm. Total serum protein was measured by refractive index. Four glass tubes were set up for each blood sample, two containing 40 µl of saline solution and two containing 50 µl of normal human serum or a serum albumin solution (40 g/l). Plasma (10 µl) was pipetted into each tube. A standard bilirubin curve was set up in the range of 0 to 200 mg/l. A tube containing 40 µl of human serum and 10 µl of saline provide a correction factor for the endogenous bilirubin and albumin present in the normal human serum. Phosphoric acid (0.6 ml) was added to the standards and samples and mixed. At least 1 min after mixing, 3 ml of ascorbic acid reagent was added to each tube and mixed again. Fluorescence short-scan measurements were made within 2 hr in quartz cuvets at: excitation 435 nm, excitation slit 6 mm, emission 480 to 520 nm, and emission slit 12 mm. Analysis of the plasma sample alone and in the presence of excess human serum albumin solution appeared to reflect the bilirubin tightly bound to albumin and the total serum bilirubin, resp. The differences between these two values is the albumin-titratable bilirubin. A typical saturation effect was observed with considerable albumin-titratable bilirubin concentrations. In samples where the circulating bilirubin was strongly bound to endogenous albumin, no change was observed when exogenous albumin was added. This method appears to provide a useful supplement to currently available procedures for the assessment of the jaundiced neonate. It is easy to perform, requires only small amounts of plasma, and the results correlate well with the clinical picture.

6215 CALORIC INTAKE AND UNCONJUGATED HYPERBILIRUBINEMIA. *(E.)* Felsher, B. F.; Carpio, N. M. (VA Hosp., Long Beach, Calif.). *Gastroenterology* 69(1):42-47, 1975.

The caloric effect observed in Gilbert's syndrome was investigated to determine its relation to a higher prefasting serum bilirubin level or the underlying uridine diphosphate glycuronyltransferase (UDPG-T) deficiency. UDPG-T assays were performed on liver biopsies from patients with Gilbert's syndrome. Diet studies were performed on 10 patients with Gilbert's syndrome, in 7 patients with hemolysis, and in 13 normal subjects. The subjects fasted for 48 hr prior to measurement of the serum total and direct reacting bilirubin concentration. Two normal subjects were also treated with novobiocin prior to and while fasting. In patients with Gilbert's syndrome and in normal subjects the increase in total serum bilirubin after a 48-hr fast was statistically significant, but the absolute increase in serum bilirubin concentration after a fast was much greater in Gilbert's syndrome compared with normal subjects. In patients with hemolysis, the increase in mean serum bilirubin level after fasting, in spite of a higher mean prefasting level, was significantly less than that obtained in the group with Gilbert's syndrome and only slightly greater than in the normals. Disparate results were obtained in two additional patients with hemolysis and unconjugated hyperbilirubinemia. The reciprocal relations of caloric intake to the serum bilirubin level demonstrated by these patients more closely resembled that observed in the patients with Gilbert's syndrome than the other patients with hemolysis. A comparison of hepatic UDPG-T activities in all subjects showed that the enzymic activities in the two patients with hemolysis and an atypical caloric effect were reduced to levels comparable to Gilbert's syndrome. In two normal subjects, the serum total bilirubin concentrations increased, resp., 0.7 and 0.6 mg/100 ml after novobiocin, and 4.4 and 3.3 mg/100 ml after a combination of fasting and novobiocin. The serum conjugated fractions were not increased. The results indicate that unconjugated hyperbilirubinemia *per se* is not responsible for the exaggerated response in Gilbert's syndrome and suggest that the underlying reduction in UDPG-T activity is the responsible factor. Fasting appears to differentiate Gilbert's syndrome from hemolytic jaundice as well as from normal subjects, irrespective of the initial serum bilirubin concentration.

6216 GLUCOCORTICOIDS AND BILIRUBIN METABOLISM IN JAUNDICE. *(Pol.)* Pirwitz, B. (Clin. Gastroenterol. Metabol., Postgrad. Training Ctr. Phys., Warsaw, Poland). *Przegl. Lek.* 31(10):865-868, 1974.

LIVER AND BILIARY TRACT

Nonviral Hepatitis and Hepatic Injury

6217 ISONIAZID-ASSOCIATED HEPATITIS: SERUM ENZYME DETERMINATIONS AND HISTOLOGIC FEATURES. *(E.)* Lewis, J. E.; Mello, P.; Knauer, C. M. (Santa Clara Valley Med. Cent., San Jose, Calif.). *West. J. Med.* 122(5):371-376, 1975.

The frequency and severity of the physiologic, histologic, and symptomatic features of isoniazid-associated hepatitis were studied prospectively in 208 patients treated for up to 12 months with isoniazid for tuberculosis prophylaxis. General clinical evaluations and SGOT evaluations were performed on all patients prior to the initiation of isoniazid treatment and 1, 2, 3, 6, 9, and 12 months thereafter. Serum bilirubin, alkaline phosphatase, SGPT, and hepatitis-associated antigen (HAA) were also measured in those with elevated SGOT levels. Elevated SGOT levels developed in 43% of the 47 adults who developed symptoms of hepatitis, 16% of the 109 asymptomatic patients, and 18% of the 142 patients without history of alcohol abuse. Six patients had elevated SGOT levels before initiation of isoniazid therapy, 12 patients with normal pretreatment SGOT levels had single or nonconsecutive elevations in SGOT during therapy, and 19 patients with normal pretreatment SGOT levels had two or more consecutive elevations in SGOT during therapy. The SGPT levels were elevated in eight of these patients, but alkaline phosphatase and bilirubin were generally within normal limits and HAA was negative. Percutaneous liver biopsy was done in eight patients with persistent SGOT elevation during isoniazid therapy; nonspecific hepatitis was evident in five, slight portal fibrosis and early bile duct proliferation were found in another, and mild to moderate microvesicular fatty metamorphosis were observed in the other two. Among the 33 isoniazid-treated children, SGOT abnormalities developed in two. It is recommended that monthly clinical evaluations be made in patients receiving isoniazid. In symptomatic patients, liver function tests should be performed and in cases of prolonged elevations in hepatic enzymes, bilirubin, and/or alkaline phosphatase, isoniazid administration should be discontinued. Liver biopsies may be indicated in these patients, particularly if the liver function parameters do not return to normal values after discontinuation of isoniazid.

6218 INCREASED INCIDENCE OF ISONIAZID HEPATITIS IN RAPID ACETYLATORS: POSSIBLE RELATION TO HYDRAZINE METABOLITES. *(E.)* Mitchell, J. R.; Thorgeirsson, U. P.; Black, M.; Timbrell, J. A.; Snodgrass, W. R.; Potter, W. Z.; Jollow, D. J.; Keiser, H. R. (Lab. Clin. Pharmacol., Natl. Heart Lung Inst., Bethesda, Md.). *Clin. Pharmacol. Ther.* 18(1):70-79, 1975.

To determine whether susceptibility to hepatic injury is correlated with the rapid acetylation of isoniazid, 26 non-Oriental patients who had recovered from probable or possible isoniazid hepatitis were genetically phenotyped as rapid or slow metabolizers of isoniazid, based on their ability to acylate orally administered sulfamethazine (40 mg/kg). Then, to determine whether other differences occur in the metabolism of isoniazid in rapid and low acetylators, radiolabeled isoniazid and acetylisoniazid (5 mg/kg) were given p.o. to seven adult male volunteers, and the urinary metabolites were isolated and identified by paper chromatography and mass spectrometry. Among the 21 subjects who had previously suffered probable isoniazid liver injury, 86% displayed the rapid phenotype for sulfamethazine acetylation. Of the five subjects who had suffered possible isoniazid liver injury, 60% were rapid acetylators; the expected frequency was 45%. Analysis of the urinary isoniazid metabolites in the second study showed that the amounts of isoniazid hydrozones excreted approximately paralleled the isoniazid excretion in both slow and rapid acetylators. However, the excretion of acetylisoniazid and isonicotinic acid and its glycine conjugate were inversely related to the amount of isoniazid excreted. Acetylisoniazid metabolism was the same in both slow and rapid acetylators, no hydrazones being formed after acetylisoniazid administration. It is suggested that the release of the hepatotoxic hydrazino moiety of isoniazid in man is responsible for isoniazid liver injury.

6219 QUINIDINE HEPATITIS. *(E.)* Handler, S. D.; Hirsch, N. R.; Haas, K.; Davidson, F. Z. (Montefiore Hosp. Med. Cent., Bronx, N.Y.). *Arch. Intern. Med.* 135(6):871-872, 1975.

A 72 yr-old woman receiving quinidine (200 mg/6 hr) for 16 months developed abnormal levels of SGOT, alkaline phosphatase and LDH, which returned to normal upon discontinuation of the drug. Upon challenge with 200 mg of quinidine, the levels became abnormal. Prior to therapy, SGOT was within normal limits (10-50 mIU/ml), but 7 months after initiation, SGOT was 367 mIU/ml. During the following 9 months, SGOT ranged from 490 to 795 mIU/ml and the patient suffered anorexia and a 4.5 kg weight loss. At this time, other medications included diphenhydramine, triamterene, hydrochlorothiazide, meprobamate, estrogen, digoxin, nitroglycerin and Ornade. All medications, except digoxin, were discontinued 2 weeks prior to admission. At that time, SGOT was greater than 300 mIU/ml; alkaline phosphatase was raised to 110 mIU/ml, and LDH was raised to 417 mIU/ml. On admission, SGOT was 155 mIU/ml; alkaline phosphatase was 93 mIU/ml and LDH was 220 mIU/ml. Counter immunoelectrophoresis for hepatitis B antigen and antibody was negative. Percutaneous liver biopsy revealed focal areas of hepatocellular necrosis and replacement by Kupffer cells, suggesting active, acute nonspecific hepatitis. After liver function tests returned to normal for 2 weeks, 200 mg of quinidine was given as a challenge. Within 24 hrs, anorexia, vomiting and weakness developed and SGOT climbed to 110 mIU/ml by 72 hrs. Quinidine appears to have a hepatotoxic effect which currently must be labeled as idiopathic.

6220 IS LIVER INJURY PRODUCED BY HIGH-CALORIE INFUSION THERAPY? *(Ger.)* Pfeffer, H. (Surg. Clin., Univ. Giessen, Germany). *Diagnostik* 8(8):307-311, 1975.

After a 12-14 hr fast, five groups of metabolically normal male and female mongrel dogs were infused for 6 hr/day over a 4-day period with the following: (1) 1 ml/kg/hr of 0.9% NaCl; (2) 2 ml/kg/hr of a high-calorie (2.216 kcal/kg/hr) solution containing glucose (0.06 g/kg/hr) + fructose (0.14 g/kg/hr) + xylotol (0.20 g/kg/hr) + ethanol (0.08 g/kg/hr); (3) 4 ml/kg/hr of a high-calorie (4.432 kcal/kg/hr) solution containing glucose (0.20 g/kg/hr) + fructose (0.28 g/kg/hr) + xylitol (0.40 g/kg/hr) + ethanol (0.16 g/kg/hr); (4) 4 ml/kg/hr of the high-calorie solution + 2.5 mg ATP (1.185 mg PO_4^{-3}/kg/hr); and

(5) 4 ml/kg/hr of the high-calorie solution + 0.72 ml Sörensen buffer (14.400 mg/kg/hr PO_4^{-3}). High-calorie solutions also contained Na^+, K^+, Mg^{++}, and Cl^-. On days 1 and 3, the activities of the following enzymes were determined on blood samples taken before infusion and 1, 2, 4, and 8 hr thereafter: SGOT, SGPT, alkaline phosphatase, LDH, leucine aminopeptidase (LAP), γ-glutamyl transpeptidase and cholinesterase. Blood samples were also taken on day 5 before liver biopsies were removed. In group (2), the mean value for SGPT increased significantly above the normal range on days 3 and 5, but SGOT, LDH, and LAP activities remained unchanged, indicating the absence of either liver injury or cholestasis. Peripheral fatty liver was present in 1/6 biopsies. This may have been due to failure of the dog to eat enough or to increase lipolysis induced by ethanol. In group (3), SGOT, SGPT and AP levels were significantly elevated on days 1, 3, and 5, indicating parenchymal liver damage with liver cell necrosis. Fatty liver was present in all dogs and may have been dietary in origin; two dogs had hepatic necrosis. The activities of all serum enzymes studied were considerably lower and liver biopsies showed fewer changes in dogs given high-calorie infusions + phosphate (groups four and five). Increased alkaline phosphatase activities in groups 2-5 were attributed to enzyme induction produced by the initial decrease in serum phosphate concentrations which, in turn, was caused by the high intake of carbohydrates and their metabolization. The hepatotoxic effect of solutions used for high-calorie infusion can be reduced by adding ATP or Sörensen buffer. The dose of phosphate administered is responsible for this effect.

6221 HORMONAL CONTRACEPTIVES AND LIVER DAMAGE.

(Ger.) Otto, G.; Uhlig, K. (Polyclin., Dep. Minist., Berlin, Germany). *Z. Aerztl. Fortbild. (Jena)* 68(21):1181-1183, 1975.

Oral contraceptives have been prescribed for approximately 2000 women with normal histories, no evidence of hepatomegaly, and normal liver function tests. These patients were routinely followed every 6 months to determine SGOT, SGPT, and alkaline phosphatase activities. After taking oral contraceptives for 4-54 months, nine women, aged 20-37 yr, had abnormal liver function tests. A diagnosis of liver injury was confirmed by biopsy, intravenous cholangiography, or a liver specimen taken during cholecystectomy in all but two cases. The findings included diffuse fatty liver (one case), chronic persistent hepatitis (three cases), cholecystolithiasis (two cases), mild parenchymal damage (one case), cholangiolitis (one case), cholesteatosis of the gallbladder (one case), and Dubin-Johnson syndrome (one case). In four cases, patients were able to resume oral contraceptives after liver function tests had normalized. One patient stopped taking oral contraceptives, became pregnant and developed pruritis and increased alkaline phosphatase and SGPT values toward the end of pregnancy. Two months after delivery, oral contraceptives were resumed, but transaminase values increased and chronic persistent hepatitis was found on biopsy; oral contraceptives were discontinued. Oral contraceptives were also discontinued in one patient with cholangiohepatitis and one with Dubin-Johnson's syndrome and in two patients with no histological evidence of liver injury whose transaminase values increased again after a 1-month trial.

6222 PHENYLBUTAZONE AND HEPATITIS.

(E.) Fowler, P. D.; Woolf, D.; Alexander, S. (Med. Dep., Geigy Pharm., Macclesfield, England). *Rheumatol. Rehabil.* 14(2):71-75, 1975.

A case is reported of a patient who developed mild hepatitis during a comparative trial of enteric-coated and rectally administered phenylbutazone in patients with rheumatoid disease. A 69-yr-old woman with rheumatoid arthritis was treated with gold sodium thiomalate, and received a total dose of 1040 mg gold. A course of phenylbutazone was begun 2 months after stopping the gold treatment and 1 month after stopping corticosteroids. Less than 1 month later, she was admitted with epigastric pain, nausea, vomiting and generalized fatigue. On examination she had vesicular lesions similar to those seen in chickenpox; the liver was slightly enlarged and tender and remained so for 21 days. Liver function tests were carried on on two occasions about 1 month later: eosinophilia was 1869 and $4544/mm^3$, resp.; alkaline phosphatase and BSP retention were both elevated above normal limits for more than 1 month after the initial episode. Lymphocyte reactivity tests were carried out to determine the cause of jaundice, and phenylbutazone was identified as the probable causative agent. Close study of the relation of the jaundice to the drug therapy revealed that either phenylbutazone or gold sodium thiomalate malate could be incriminated, especially in view of the relative frequency of gold hepatitis and rarity of phenylbutazone hepatitis. This study indicates the difficulty of interpreting adverse reaction data, and the positive help from the lymphocyte transformation test. It is concluded that this patient should not be again exposed to phenylbutazone or related compounds, and that if gold is thought necessary, a very small test dose should first be given.

6223 JAUNDICE DUE TO ERYTHROMYCIN ESTOLATE.

(E.) Lunzer, M. R.; Huang, S. N.; Ward, K. M.; Sherlock, S. (R. Free Hosp., London, England). *Gastroenterology* 68(5):1284-1291, 1975.

A case of jaundice and abdominal pain associated with erythromycin estolate therapy is reported. A 43-yr-old man received a short course of erythromycin estolate for acute pharyngitis; 1 yr later, he experienced another attack of pharyngitis, and was again placed on the drug (250 mg/8 hr). After 24 hr, he experienced severe epigastric pain requiring hospital admission. After 48 hr, his urine became dark, and he was found to develop jaundice; transaminase and bilirubin values were elevated, and viral hepatitis was considered. A further course of the antibiotic was given on another attack of pharyngitis, and the patient again experienced epigastric pain and jaundice. Electron micrographs were taken of percutaneous liver biopsy before and after challenge with two doses of 250 mg erythromycin estolate. Pre-challenge, the general ultrastructures of the liver cells, bile canaliculi, and interlobular bile ducts were normal. A prominent degree of vesiculation was noted in periportal liver cells. About 20% of bile canaliculi, both in the centrilobular and periportal zones, exhibited a mild degree of dilatation. The portal areas showed inflammatory infiltration with presence of eosinophils immediately around the bile ducts. The results of liver function tests taken after challenge showed elevation of aspartate transaminase, alkaline phosphatase, and serum bilirubin. These findings indicate that many anatomical and cellular factors are involved in the mechanism of erythromycin estolate-induced liver injury, although the precise mechanism is not yet fully understood.

6224 GREY-SCALE ULTRASONOGRAPHY FOR MONITORING INDUSTRIAL EXPOSURE TO HEPATOTOXIC AGENTS. *(E.)* Taylor, K. J. W.; Williams, D. M. J.; Smith, P. M.; Duck, B. W. (R. Marsden Hosp., Sutton, England). *Lancet* 1(7918):1222-1224, 1975.

Preliminary results are reported demonstrating the use of grey-scale ultrasonography in the visualization of pathological lesions of the liver and spleen related to vinyl chloride exposure. Utilizing skin contact with a metallic transducer and a suitable coupling agent such as mineral oil, the liver was scanned in a series of parasagittal sections by moving the transducer through an arc. The resultant scan in a normal subject showed the normal liver consistency and, in a suitable parasagittal plane, a portal vein of normal size and appearance. In patients with portal hypertension, the portal vein was enlarged and tortuous. Although evidence of fatty infiltration and fibrosis was seen in these patients, the pathological appearance of the liver was much less obvious than that seen in patients with cirrhosis and an equivalent degree of portal hypertension. The spleen can be scanned along the 10th intercostal space with the patient lying in the right lateral position. A measure of spleen size can be obtained from the longitudinal axis. When splenomegaly is secondary to portal hypertension, it has a characteristic pattern which may be differentiated from malignant or chronic inflammatory causes of splenomegaly. These data suggest that grey-scale ultrasonography could be valuable for monitoring any liver or spleen changes related to vinyl chloride exposure. Attractive features of the ultrasound apparatus include the potential mobility in a vehicle of similar dimensions to a mobile chest x-ray unit, and the lack of ionizing radiation hazards and domestic power requirements. It is concluded that these features would permit the safe, non-invasive screening of whole populations exposed to potentially hepatotoxic agents.

6225 CARBON TETRACHLORIDE OVERDOSAGE: A CASE REPORT. *(E.)* Kennaugh, R. C. (Frere Hosp., East London, S. Afr.). *S. Afr. Med. J.* 49(15):635-636, 1975.

The successful management of liver and renal failure, ventricular fibrillation, hemorrhagic diathesis, and central nervous system agitation following carbon tetrachloride overdose in a 30-yr-old white male is described. The patient was hospitalized following the ingestion of a number of Carbrital capsules, trichloral, ethanol, and 120 ml of CCl_4. A stomach washout was performed 2 to 3 hr later. Initially 80 mg of furosemide was given i.v. every 8 hr as treatment for renal failure; after 1 day this was increased to 1 g every 12 hr and was stopped on day 5 when diuresis began and KCl was added to the daily i.v. infusion fluid. Treatment for hepatic failure included i.v. vitamin K (20 mg) administration on admission, followed by p.o. vitamin BCo and vitamin C administration and p.o. neomycin administration on day 5. I.v. verapamil (10 mg, twice daily) was given after Digoxin failed to control atrial fibrillation; spontaneous reversion to sinus rhythm occurred on day 22. I.v. (later oral) diazepam (10 mg every 6 hr) was necessary to control the patient's agitation and from day 4, i.v. Solu-Medrol (125 mg twice daily) was administered as a general treatment. The hemoglobin decreased slowly during hospitalization, the white count remaining high until discharge and the platelets falling gradually but increasing prior to discharge (29 days after admission). Most deaths following CCl_4 poisoning occur within 3 to 10 days as the result of massive liver necrosis or acute renal failure. If the toxic effects arising from CCl_4 poisoning are known and looked for, they can be treated successfully *ad initio.*

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

6234 THE BALANCE OF TRACE ELEMENTS IN CHILDREN WITH INFECTIOUS HEPATITIS. *(Ukr.)* Trishkova, L. O. (Kiev Med. Inst., USSR). *Pediatr. Akush. Ginekol.* 35(2):16-18, 1973.

A balance study for trace elements in 20 children (nine boys and 11 girls, aged 6-11 yr) and in five healthy children was performed by spectroanalysis for copper, manganese, vanadium, nickel, and lead in food, feces, urine, and blood. The iron content was determined by the colorimetric Babenko method. It was observed that during illness, infected children receive in general fewer trace elements from their food than healthy children. During acute period of infection, or immediately after, iron, vanadium, nickel, lead, and copper leave the bodies of infected children at increased rates, through feces and urine, so that the balance of the trace elements in the bodies of children with infectious hepatitis is significantly offset, and requires additional supplement.

6235 SEROLOGIC CHARACTERIZATION OF PATIENTS WITH TWO EPISODES OF ACUTE VIRAL HEPATITIS. *(E.)* Karvountzis, G. G.; Mosley, J. W.; Redeker, A. G. (Univ. South. California Sch. Med., Los Angeles). *Am. J. Med.* 58(6):815-822, 1975.

Twenty-eight patients with two distinct episodes of illness compatible with acute viral hepatitis were reviewed to determine if presently available serologic techniques identified both episodes as attributable to hepatitis B virus, either because of recurrence or reinfection. No distinction was found between the first and second bouts with respect to clinical characteristics, abnormalities of liver function or epidemiologic background. Testing of serum specimens obtained during each of the two acute episodes, the interval between the two episodes and the period subsequent to the second, by sensitive procedures for hepatitis B surface antigens (HB_sAg) and their corresponding antibodies (anti-HB_sAg) permitted the following classification: 13 of 28 patients experienced first bouts serologically classifiable as due to hepatitis B virus; 11 had second bouts serologically classifiable as due to the hepatitis B virus; 2 patients had two episodes which were both serologically indeterminate; and 2 patients had two bouts neither of which appeared compatible with hepatitis B virus infection by present criteria. No patient had a second episode for which the HB_sAg and anti-HB_sAg data suggested hepatitis B virus recurrence or reinfection. These results do not favor speculation that the hepatitis B virus can account for repeated episodes of acute icteric hepatitis.

6236 RELATIONSHIP OF HEPATITIS B ANTIGEN IN CIRRHOSIS AND HEPATOMA IN THAILAND. AN ETIOLOGICAL SIGNIFICANCE. *(E.)* Chainuvati, T.; Viranuvatti, V.; Pongpipat, D. (Siriraj Hosp., Bangkok, Thailand). *Gastroenterology* 68(5):1261-1264, 1975.

A study was undertaken to determine the possible relation between hepatitis B surface antigen (HB_sAg), cirrhosis, and hepatoma. In a study of 221 patients, detectable HB_sAg was found in 16.3% of 49 patients who had hepatoma associated with cirrhosis. None of the 8 hepatoma patients without cirrhosis had detectable HB_sAg in the serum. When known causes of cirrhosis were excluded, HB_sAg was present in 18% of 22 patients. Positive α_1-fetoprotein (AFP) was found in 25 of 49 cases (51%) of hepatoma with cirrhosis but was found in only 1 of 8 cases (12.5%) of hepatoma without cirrhosis. Of 25 patients whose AFP was positive, HB_sAg was also present in 7. The latter was detected in only 1 of 24 patients in whom AFP was not detected. These results suggest that HB_sAg is closely associated with hepatomas in cirrhotic patients but not in noncirrhotic patients with hepatoma.

6237 THYMUS-DERIVED LYMPHOCYTES IN TYPE B ACUTE VIRAL HEPATITIS AND HEALTHY CARRIERS OF HEPATITIS B SURFACE ANTIGEN (HB_sAg). *(E.)* Wicks, R. C.; Kohler, P. H.; Singleton, J. W. (Univ. Colorado Med. Cent., Denver). *Am. J. Dig. Dis.* 20(6):518-522, 1975.

To assess thymus-derived (T) lymphocyte function in hepatitis B infection, lymphocytes from 8 patients with acute viral hepatitis type B and 8 healthy carriers of the hepatitis B surface antigen (HB_sAg) were compared with 13 normal controls using phytohemagglutinin-induced blast cell transformation and sheep-cell rosette formation. The patients with acute hepatitis and the healthy carriers had serum HB_sAg detected by immunoelectrodiffusion within 1 week of *in vitro* lymphocyte testing. Overall T lymphocyte cell-mediated immune function was similar with the *in vitro* assays in all three groups, except for decreases in total T cells in 2 patients with acute disease. Consequently, if a defect in cellular immunity exists in normal controls with persistent hepatitis B infection, it is probably specific for the antigens of the hepatitis B virus and not related to a generalized impairment of T-lymphocyte function.

6238 FIBRINOGEN METABOLISM IN ACUTE HEPATITIS AND ACTIVE CHRONIC HEPATITIS.

(E.) Clark, R. D.; Gazzard, B. G.; Lewis, M. L.; Flute, P. T.; Williams, R. (King's Coll. Hosp. Med. Sch., London, England). *Br. J. Haematol.* 30(1):95-102, 1975.

Coagulation studies, including those of radioactive fibrinogen metabolism, were performed in 7 patients with acute viral hepatitis and 12 with chronic active hepatitis. An increased fractional catabolic rate for fibrinogen was observed in 4 patients from the first group, and 7 from the second. In chronic active hepatitis, the catabolic rate was increased in those patients with the greatest degree of hepatic necrosis as demonstrated by raised serum aminotransferase levels. The correlation between the fibrinogen catabolic rate and extent of disease was less clear-cut in acute hepatitis, although the 2 patients with aspartate aminotransferase values >1000 IU/ml had the highest catabolic rates. There was no correlation between the rate of fibrinogen catabolism and the standard clotting tests, but the serial dilution of protamine sulfate test (indicating the presence of fibrin monomers in the circulation) was consistently positive in those cases where the catabolic rate was increased. These data, showing a correlation between an increased fractional catabolic rate and both a positive test for fibrin monomer and the plasma aminotransferase levels in active chronic hepatitis, suggest that this gradation in severity of intravascular coagulation may in some way be related to the severity of hepatic necrosis.

6239 ACUTE FULMINANT HEPATIC FAILURE: POTENTIAL THERAPEUTIC ROLE OF HEMOPERFUSION

(E.) Willson, R. A. (Dep. Med., Univ. Washington, Seattle). *Gastroenterology* 69(1):244-248, 1975.

Hemoperfusion therapy techniques in the treatment of acute fulminant hepatic failure are discussed. The technique consists of perfusing whole blood through columns containing various toxin-removing adsorbants. Charcoal hemoperfusion uses activated charcoal coated with a thin biocompatible membrane to prevent loss of platelets and leukocytes in the charcoal, and to prevent escape of charcoal particles into the circulation. The technique is an extension of standard hemodialysis, and has a theoretically greater dialysance. Its effectiveness is dependent on whether the toxins are water-soluble, whether they will permeate the membrane, and whether they will be adsorbed by the charcoal (urea and ammonia will not). In studies already done, the technique was found to be simple, safe, and well tolerated by the patients. There was a 37% survival rate (of 37 patients with stage IV encephalopathy), as compared to a 13% survival rate (of 97 patients with stage III-IV encephalopathy) without hemoperfusion. Hemoperfusion using cation exchange resins will lower the blood ammonia concentration, but causes a decrease in circulating leukocytes and platelets. Encapsulating the resins with a biocompatible membrane is a probable solution. Anion exchange and uncharged resins have been shown to be superior to dialysis in removing protein-bound BSP, bilirubin, and bile acids; however, loss of leukocytes and platelets is significant. A suggested solution is to first separate the plasma by continuous centrifugation, or to develop more biocompatible resins. Albumin bound to agarose beads has been shown to remove protein-bound substances from blood with a minimal loss of leukocytes and platelets. It is concluded that hemoperfusion is a potentially useful technique in the treatment of acute liver failure.

6240 VIRAL HEPATITIS WITH INTRACYTOPLASMIC CHOLESTASIS AND CHOLESTEROL CRYSTALS IN A DRUG ADDICT.

(E.) Livni, N.; Steigbuegel, D.; Levij, I. S. (Hebrew Univ. Hadassah Med. Sch., Jerusalem, Israel). *J. Pathol.* 116(1):47-50, 1975.

A case is presented of intracytoplasmic cholestasis and cholesterol crystals associated with viral hepatitis. A 16-yr-old female presented with jaundice, mild hepatosplenomegaly, and a temperature of 38 C, associated with upper abdominal pain, anorexia, nausea and vomiting. There was a history of drug abuse, and the patient was known to have used the syringe of a person with jaundice. There was an episode of similar symptoms three months prior to admission. Light microscopy of a liver biopsy showed a few acidophilic bodies and a minimal lymphocytic infiltrate compatible with a diagnosis of viral hepatitis. Thin sections revealed extensive intracellular bile pigment. Electron microscopy revealed focal degeneration of hepatocytes, masses of intracytoplasmic, osmiophilic, electron-dense material (presumably bile pigment), acidophilic round bodies (presumably necrotic cells), and round or oval virus-like particles about 500 to 800 Å in diameter with electron-light cores free in the cytoplasm. Also, numerous elongated, rhomboidal or rectangular empty clefts, 1 to 1.5 cm long,were found in the cytoplasm. They were surrounded by a layer of granular, electron-dense material and apparently represented localizations of cholesterol crystals dissolved during preparation of the tissue. Serum cholesterol level of the patient was normal. It is concluded that the intracellular precipitation of cholesterol crystals may have been due to an abnormal bile salt-cholesterol ratio related to intracellular cholestasis.

6241 HEPATITIS VACCINE: A NOTE OF CAUTION.

(E.) Zuckerman, A. J. (no affil.). *Nature* 225(5504):104-105, 1975.

Current work toward the development of a safe and effective vaccine against viral hepatitis type B is reviewed. The ability of the isolated viral coat protein to challenge the body's immune mechanism in the same way as the whole infectious agent is known, and some research has developed a method for using purified 20 nm hepatitis B surface antigen particles which are free of detectable nucleic acid as immunogens. However, it is known that a variable amount of host protein and perhaps even carbohydrate may be complexed with hepatitis B viral protein in considerable quantities. If this is so, then these host proteins may include various pre-existing structures of the liver cell and may thus induce undesirable immunological reactions. There may be a similarity between the carbohydrate hapten, or the lipoprotein components found in purified fractions of the antigen, and those carbohydrate and lipoprotein antigens of normal cell surfaces, which would lead either to a degree of tolerance, or might initiate an autoimmune reaction. It is indicated that the immunological mechanisms and the presence of antibodies reacting with various tissue components may be involved in the pathogenesis of liver damage. Therefore, it may be undesirable to employ preparations of hepatitis B surface antigen which contain host cell components for immunization against this infection. Careful evaluation of immunization preparations in appropriate non-human primates is essential before small trials are undertaken in human subjects. These experimental trials should be directed not only at the protective efficacy of such immunogens but also should include careful assessment of all their effects on the immune system.

6242 THE RISK OF HEPATITIS FOLLOWING TRANSFUSION OF BLOOD POSITIVE FOR HEPATITIS B ANTIBODIES. *(Ger.)* Schlaak, M.; Lehmann, H.; Schober, H. (Med. Clin., Univ. Kiel, Germany). *Verh. Dtsch. Ges. Inn. Med.* 80:469-470, 1974.

Of 48 patients who underwent heart surgery with extracorporeal circulation, 25 developed hepatitis after incubation periods ranging from 28 to 110 days (mean 70 days); tests for hepatitis B antigen (HBAg) or antibody (HBAb) were positive in 90%. These patients received 3 to 42 U of blood (mean, 12.4 U/patient). There was a definite relation between the number of blood units received and the hepatitis risk in this group of patients. By using the maximum likelihood technique, the hepatitis risk was calculated at 50% with 10 U, and the risk/U was 6.4%. Radioimmunoassays showed that HbAg was present in only 1.1% of blood units administered to these patients, but HBAb was detected in 6%. In a larger group of 66 patients, eight had received at least 1 U of HBAg-positive blood and all eight developed hepatitis. Hepatitis occurred in 23 of these 66 patients, and in 14 of the 26 given HBAb-positive blood but in only nine of the 31 receiving HBAb-negative blood. However, ten patients given blood containing neither HBAg nor HBAb also developed hepatitis. By eliminating the use of blood containing either HBAg or HBAb, it is considered that the incidence of hepatitis could be reduced 70 to 80% in patients undergoing open-heart surgery.

6243 CHANGES IN IMMUNOGLOBULINS G, M, AND A AS ACUTE HEPATITIS EVOLVES TO CHRONIC HEPATITIS. *(Ger.)* Berthold, H.; Rotermund, H. M.: Maier, P.; Stiess, G.; Oehlert, W. (Hyg. Inst., Univ. Freiburg, Germany). *Verh. Dtsch. Ges. Inn. Med.* 80:474-476, 1974.

Quantitative immunoglobulin determinations were performed by radial immuno-diffusion on blood from patients with various forms of acute and chronic hepatitis to determine whether there is any relation between the humoral immune reaction in acute hepatitis and the further course of the disease. Patients consisted of 16 with uncomplicated acute hepatitis, six with acute hepatitis persisting for more than 4 months, four with chronic persistent hepatitis of more than 12 months duration, four with chronic aggressive hepatitis who recovered clinically and histologically without treatment, five with chronic aggressive hepatitis which had been observed to evolve from acute hepatitis, and seven with later stages of chronic aggressive hepatitis. Although the number of patients studied is too small to determine whether findings are statistically significant, there appeared to be a correlation between the primary humoral immune response and the course of acute hepatitis. Acute hepatitis in which the initial increase in IgM concentrations was small tended to evolve into the chronic persistent form, while patients with acute hepatitis accompanied by modest increases in immunoglobulin levels and a histological diagnosis of "chronic aggressive hepatitis" may recover spontaneously. Excessive increases in immunoglobulin levels at the onset of hepatitis suggest that evolution to chronic aggressive hepatitis may occur.

6244 SPONTANEOUS LYMPHOCYTE PROLIFERATION IN ACUTE AND CHRONIC HEPATITIS. *(Ger.)* Sodomann, C. P.; Rother, M.; Havemann, K. (Med. Clin., Univ. Marburg, Germany). *erh. Dtsch. Ges. Inn. Med.* 80:1638-1641, 1974.

Lymphocyte proliferation in the absence of phytohemagglutinin (PHA) was studied in peripheral blood cultures from patients with Australia antigen (AuAg)-positive and AuAg-negative acute and chronic hepatitis by measuring ^{3}H-thymidine incorporation. Cultures contained 15% autologous serum or 15% pooled AB serum. Spontaneous lymphocyte proliferation occurred more often than in controls during the first 10 days after the onset of jaundice and before transaminase activities increased in patients with acute hepatitis B. This increase was more pronounced in the presence of homologous, rather than autologous, serum. The reason for this is not clear, but it may be due to the inhibition of increased DNA synthesis by AuAg-positive serum. In later stages of hepatitis B, values returned to the normal range. No difference in spontaneous lymphocyte proliferation was observed between early and later stages of hepatitis A, and there was little difference between results obtained in cultures containing autologous and those containing homologous serum. In all but a few patients with AuAg-positive chronic aggressive hepatitis, spontaneous lymphocyte proliferation was increased; the exceptions were patients with histological evidence of cirrhosis. Values were in the normal range in patients with AuAg-negative chronic aggressive hepatitis and were below the normal range in patients developing cirrhosis. With one exception, lymphocyte proliferation was within normal limits in cultures obtained from patients with chronic persisttent hepatitis, no matter whether AuAg was present or not. Spontaneous lymphocyte proliferation was significantly decreased in cultures from three patients with alcoholic cirrhosis and was greatly increased in cultures from three patients with infectious mononucleosis associated with hepatitis. These findings indicate that a large number of patients with AuAg-positive chronic aggressive hepatitis have lymphocytes which not only show increased reactivity to PHA, but also synthesize DNA at increased rates.

6245 IMMUNOGLOBULINS AND AUSTRALIN ANTIGEN IN VARIOUS FORMS OF HEPATITIS AND IN CIRRHOSIS. *(Ger.)* Reis, H. E.; Bertrams, J.; Selmair, H.; Wiese, W.; Kuwert, E.; Hirche, H. (Munic Hosp., Kassel, Germany). *Med. Welt.* 25(31-32):1277-1279, 1974.

Immunoglobulins were measured by radial immunodiffusion and hepatitis B antigen (HBAg) titers by the complement fixation reaction on blood from patients with various forms of acute and chronic hepatitis and cirrhosis to determine whether there is an inverse correlation between immunoglobulin levels and the appearance of HBAg. Blood was taken from 46 patients with acute and 25 with protracted hepatitis, 46 with chronic persistent and 58 with chronic aggressive hepatitis, 49 with cryptogenic and 18 with posthepatitic cirrhosis, and from 93 controls. Statistical analysis was performed logarithmically since, with the Kolmogoroff-Smirnoff test, immunoglobulin values are better described by a logarithmic, rather than a nonlogarithmic, normal distribution. Individual geometric means were compared by using the Duncan test. In chronic aggressive hepatitis and cryptogenic and posthepatitic cirrhosis, mean IgG and IgA values were significantly higher than in controls. IgG levels were also increased, but not to the same extent, in acute hepatitis. The greatest increases in IgM levels occurred in acute and protracted hepatitis, but significant increases were also apparent in chronic aggressive hepatitis and cryptogenic and posthepatitic cirrhosis; a smaller, but still significant, increase occurred in chronic persistent hepatitis. HBAg was detected in 43.4% of patients with acute hepatitis, 37.0% with protracted hepatitis, 72.6% with chronic persistent hepatitis, 48.0% with chronic aggressive hepatitis, and in 26.7% of the patients with both forms of cirrhosis. A comparison of immunoglobulin values in HBAg-positive blood with those in HBAg-negative blood showed no significant differences for any of the three immunoglobulins in any of the diseases considered. Similarly, no correlation was found between HBAg titers in chronic persistent and chronic aggressive hepatitis and the individual immunoglobulin levels. These findings conflict with others reported in the literature. Since no relation was observed between elimination of HBAg and immunoglobulin levels, increases in immunoglobulin levels occuring in various forms of hepatitis and cirrhosis must be induced by other antigens. It is suggested that the almost complete lack of immune response in chronic persistent hepatitis and reduced HBAg elimination in chronic aggressive hepatitis may be genetically determined, possibly by antigens in the histocompatibility system.

6246 HEPATITIS-B VIRUS AND INDIAN CHILDHOOD CIRRHOSIS. *(E.)* Nayak, N. C.; Roy, S.; Ramalingaswami, V.; Sachdeva, R. (All India Inst. Med. Sci., New Delhi). *Lancet* 2(7925):109-111, 1975.

Electron microscopy and immunospecific and orcein staining procedures were used to look for the components of hepatitis-B virus in the livers of children suffering from Indian childhood cirrhosis. The material consisted of 9 necropsy samples, 15 percutaneous needle biopsies, and 5 fresh-frozen liver biopsies. Immunostaining revealed neither the core nor surface component of hepatitis-B virus in any of the livers, and orcein staining from hepatitis-B antigen was also negative in all but one case. Coarse nonantigen granules, characteristic of degeneration hepatocytes, were often present, particularly in the necropsy material. Electron microscopic examined revealed no particles conforming in ultrastructural appearance to the hepatitis-B virus core antigen, although in a few cases occasional hepatocytes showed nonviral inclusions. The hepatocytic cytoplasm showed marked degenerative changes in the various organelles, but no proliferation of the smooth endoplasmic reticulum and no intracisternal structures resembling hepatitis-B surface antigen. These data, in conjunction with the other features of the disease, suggest that hepatitis-B virus infection plays no significant role in the etiology of Indian childhood cirrhosis.

6247 HEPATIC DYSFUNCTION IN RECIPIENTS OF RENAL ALLOGRAFTS. *(E.)* Berne, T. V.; Chatterjee, S. N.; Craig, J. R.; Payne, J. E. (Univ. Southern California Sch. Med., Los Angeles). *Surg. Gynecol. Obstet.* 141(2):171-175, 1975.

Findings of hepatic dysfunction in 18 of 42 recipients of renal allografts were analyzed with particular emphasis on the cause and results of altering the drug therapy. Following transplantation, immunosuppresive therapy consisted of prednisone and azathioprine. After an initial dose of 5 mg/kg of azathioprine, the patients received maintenance doses between 2.5 and 3.0 mg/kg/day. Prednisone was given at a dose of 2 mg/kg/day, tapered to 0.5 mg/kg/day by the end of the first month, and was reduced to 0.3 mg/kg/day by 6 months. Rejection was treated i.v. with methylprednisolone pulse therapy and the reinstitution of higher p.o. doses of prednisone. Hypertension frequently was treated with up to 2 g of methyldopa/day. Patients with thoracic roetgenographic evidence of primary pulmonary tuberculosis were given 300 mg of isoniazid/day. Evidence of a hepatic dysfunction was based on serum transaminease levels greater than 200 IU or total serum bilirubin levels greater than 2 mg%. In ten patients, hepatic dysfunction occurred while the clinical course and renal function were otherwise stable. In this group, cyclophosphamide was substituted for azathioprine, and other potentially hepatotoxic drugs were discontinued. Indexes of hepatic function improved in all of these patients, and there was no deterioration of renal function. Of 11 patients with hepatic tissue available for histopathologic study, six demonstrated changes suggestive of viral hepatitis. Two had cholestasis, suggestive of drug injury, while in three others, changes were nonspecific. Only three of the 18 patients with hepatic dysfunction were persistently hepatitis B surface antigen-positive as measured by counterimmunoelectrophoresis. Cytomegalovirus was grown from the blood within 1 month after the first detection of abnormalities of the liver in five patients, and complement-fixing antibody titer rose in six of eight patients studied. All of the five patients with a histopathologic finding of viral hepatitis had evidence of cytomegalovirus infection, while none was positive for hepatitis B surface antigen. Although there is no clear cause for the hepatic dysfunction of renal allograft recipients, the results show that discontinuation of potentially hepatotoxic drugs is associated with improvement.

6248 ANTIBODY TO HEPATITIS-B CORE ANTIGEN IN PATIENTS WITH PRIMARY HEPATIC CARCINOMA. *(E.)* Maupas, P.; Larouze, B.; London, W. T.; Werner, B.; Millman, I.; O'Connell, A.; Blumberg, B. S.; Saimot, G.; Payet, M. (Fox Chase Cancer Cent., Philadelphia, Pa.). *Lancet* 2(7923):9-11, 1975.

Antibody to hepatitis-B core antigen (anti-HB_c) was assayed in the serum of 153 patients with primary hepatic carcinoma and in 238 controls from Hong Kong, West Africa, and the United States. All sera were tested by counter-electrophoresis and immunodiffusion against hepatitis-B core antigen (HB_cAg) extracted from the liver of a patient with chronic hepatitis. Sera which gave equivocal results were then tested by counter-electrophoresis against HB_cAg Amicon concentrate. Anti-HB_c was detected in 114 of the primary hepatic carcinoma patients, the percentage of positive patients being over 90% in Senegal and about 70% in Mali and Hong Kong. Of 21 American patients, only five were positive for anti-HB_c and one of these was Chinese while another was Puerto Rican. Among the controls, 20-68% of those from Asia and Africa were positive for anti-HB_c, while only 4% of those from the United States were positive. The data, in conjunction with previous findings, support the hypothesis that chronic infection with hepatitis-B virus is etiologically related to primary hepatic carcinoma, especially in Asia and Africa, although other factors must also be involved. With the development of a vaccine against the hepatitis-B virus, prevention of many cases of primary hepatic carcinoma may, therefore, be a realistic expectation.

6249 LYMPHOCYTE STIMULATION IN HEPATITIS B INFECTIONS. *(E.)* Tong, M. J.; Wallace, A. M.; Peters, R. L.; Reynolds, T. B. (Univ. Southern California Sch. Med., Los Angeles, Calif.). *N. Engl. J. Med.* 293(7):318-321, 1975.

Cell-mediated responses in patients with acute and chronic forms of Type B hepatitis were tested by lymphocyte transformation to purified hepatitis surface antigen (HB_sAg) and to phytohemagglutinin by dinitrochlorobenzene sensitization and by response to skin test antigens. Stimulation of human peripheral lymphocytes by purified HB_sAg or phytohemagglutinin was measured by uptake of ^3H-thymidine. During the acute phase of Type B hepatitis, lymphocyte transformation to HB_sAg was not detected in any patients. However, all acquired *in vitro* lymphocyte reactivity to HB_sAg during the early recovery period when SGPT levels and circulating HB_sAg titers were declining. Patients with Type B chronic active hepatitis and carriers of HB_sAg and patients with chronic persistent hepatitis uniformly showed no lymphocyte transformation to HB_sAg. Lymphocyte transformation to phytohemagglutinin was normal in all groups studied. Primary sensitization with topical application of 2000 μg of dinitrochlorobenzene was achieved in all six patients during the acute phase of Type B hepatitis. A delayed skin reaction to dinitrochlorobenzene developed in eight patients with Type B chronic active hepatitis and seven patients with chronic persistent hepatitis and HB_sAg carriers who were tested. The results support the hypothesis that the clinical course of hepatitis B virus infection depends on the competency of the thymus or T-dependent lymphocyte system. Recovery from acute Type B hepatitis is associated with the development of a specific cell-mediated response to purified HB_sAg during the early convalescent period.

6289 LONG-TERM IMMUNOSUPPRESSIVE THERAPY IN CHRONIC AGGRESSIVE HEPATITIS AND CIRRHOSIS. *(Ger.)* Bannaski, H. (Kempfenhausen Priv. Clin., Germany). *Med. Welt* 25(39):1551-1555, 1974.

Changes in histological findings, transaminase values, immunoglobulins, and clinical findings were compared in 212 patients with chronic aggressive hepatitis or compensated or decompensated cirrhosis who received immunosuppressive agents and in 88 patients who received conservative therapy (bed rest, diet, and various infusions and anabolic and hepatotropic agents) for 3 months to 10 yr. Of these patients, 52% were men and 48% were women; 69% were more than 50 yr old and only six were younger than 30 yr. Immunosuppressives were given to patients with autoimmune diseases, primary biliary cirrhosis, and to patients with negative immunological findings who failed to respond to conservative therapy. Most patients in this group received cyclophosphamide or azathioprin, but some were given D-penicillamine and/or corticosteroids. A combination of azathioprin and corticosteroids is particularly recommended for cirrhosis. Initial doses of azathioprin were 50-150 mg, combined with 4-24 mg of corticosteroids. Corticosteroid dosages were then reduced as rapidly as possible to prevent serious side effects. Among patients given immunosuppressives, transaminase values improved in 90%, immunoglobulin G values improved in 80%, and histological findings improved in almost 70%. No comparable values were reported for patients receiving conservative therapy. Improvements occurred in 71% of 36 patients with compensated cirrhosis who received immunosuppressives and in 67% of 21 patients with decompensated cirrhosis. Leukopenia and thrombopenia were observed in 28% of patients given immunosuppressives, but were reversible when drug therapy was discontinued. Septicemia, mycosis, complete alopecia and gastric bleeding were observed in one patient each. Of eight patients with primary biliary cirrhosis, two died of cerebrovascular accidents, which were considered to have resulted from extremely high cholesterol levels after 7 and 9 yr of immunosuppressive therapy, resp.

6290 COMPLEMENT DETERMINATIONS IN LIVER DISEASE. *(Ger.)* Opferkuch, W.; Berger, J.; Forster, E.; Hopf, U.; Meyer zum Buschenfelde, K. H. (Dep. Med. Microbiol., Ruhr Univ. Bochum, Germany). *Z. Gastroenterol.* 13(suppl.):282-284, 1975.

Determinations of the fourth component of complement (C_4) were performed on 79 patients with histologically confirmed chronic active hepatitis, and the values were compared with those previously measured on normal controls. Since the mean C_4 concentration was only slightly decreased in chronic active hepatitis, the concentrations obtained were plotted against the percentage of patients having each concentration to obtain a distribution curve. t the maximum for the control curve, the curve for patients with hepatitis had a shoulder, suggesting hat this group of patients contained at least two ubgroups. Curves were then plotted for Australia ntigen (AuAg)-positive and AuAg-negative patients. While the curve for AuAg-positive patients followed he normal distribution, C_4 concentrations were decreased in AuAg-negative patients, but the latter group also included patients with normal C_4 concenrations. Since C_4 and the second component of omplement (C_2) are both produced in cells of the mononuclear, phagocytic system and since a similar ecrease did not occur in C_2 concentrations in AuAg-negative patients with chronic active hepatitis, t is concluded that decreased C_4 concentrations n these patients are not caused by a disorder in he synthesis of complement.

6291 CHRONIC AGGRESSIVE HEPATITIS IN CHILDHOOD. *(Ger.)* Scholz, H. (Munic. Clin., Berlin-Buch, Germany). *Kinderaerztl. Prax.* 42(11): 87-494, 1974.

In a 7-yr period, seven children (five girls and two boys, aged six months to 9.2 yr at onset) were treated for chronic aggressive hepatitis. These patients were followed for 1.7 to 7.2 yr (mean, 5.0 yr). At onset, two children had acute viral hepatitis; two others, who were completely asymptomatic, were suspected of having subclinical hepatitis because of close contact with a hepatitis patient. The other three patients were suspected of recurrences of chronic hepatitis. Hepatomegaly was present in 4 cases and splenomegaly in only one. Increased SGPT activities were the most useful laboratory test in diagnosing recurrences. Australia antigen was detected in five of these patients; the first test for this antigen was made only 4 yr after onset in the two patients with negative findings. Signs of aggressive hepatitis were found in only one of the 12 to 15 biopsies performed on three children. One patient had cirrhosis on laparoscopy, but not on biopsy. Azathioprin alone, given to three patients, produced no improvement so it was combined with prednisolone. Two of these patients gradually responded after 6 months and 1 yr, resp., but no effect was noted in the remaining child and he had a severe recurrence lasting many months. All children received prednisolone, which appeared to give better results than azathioprin, but no convincing evidence was obtained that it had any long-term effect on progression of the disease and some serious side effects occurred (steroid diabetes, bone changes, infections).

6292 INCREASED DNA SYNTHESIS IN LYMPHOCYTES IN CHRONIC ACTIVE HEPATITIS. *(Ger.)* Muerker-Alzer, G.; Schumacher, K.; Gross, R. (Med. Clin., Univ. Cologne-Lindethal, Germany). *Verh. Dtsch. Ges. Inn. Med.* 80:1636-1638, 1974.

DNA synthesis was studied by measuring ^{14}C-thymidine incorporation in the absence of phytohemagglutinin(PHA) in 48-hr peripheral lymphocyte cultures from 76 patients with chronic aggressive hepatitis or active cirrhosis. In cultures from 24 of these 76 patients the rate of DNA synthesis was significantly faster than that in cultures from 48 controls. No correlation was found between this increase in DNA synthesis and any of the immunological parameters studied (immunoglobulins; antinuclear, antiglomerular, or antivascular antibodies; or hepatitis B antigen or antibody). PHA stimulation was not reduced in patients with *in vivo*-activated lymphocytes. In follow-up examinations, performed on 12 patients with *in vivo*-activated lymphocytes, clinical improvements, which occurred in four cases, were accompanied by normalization of resting DNA synthesis. No appreciable change occurred in lymphocytes from the remaining eight patients who died in hepatic coma during the observation period. *In vivo*-activated lymphocytes were large cells with round- or bean-shaped nuclei and resembled blast cells after PHA stimulation. Since these lymphocytes did not form rosettes spontaneously with sheep RBC, it is likely that they were B-lymphocytes. *In vivo*-activated lymphocytes are considered to be a manifestation of an immune reaction occurring in chronic aggressive hepatitis.

6293 TREATMENT OF CHRONIC AGGRESSIVE HEPATITIS WITH D-PENICILLAMINE.

(Ger.) Heckers, H.; Gerhardt, H.; Leinweber, B.; Matthes, K. J. (Cent. Intern. Med., Univ. Gottingen, Germany). *Verh. Dtsch. Ges. Inn. Med.* 80:506-510, 1974.

D-penicillamine was used in the treatment of 32 patients, most of whom were hospitalized with chronic aggressive hepatitis and had been treated unsuccessfully with other drugs. Starting with 900 mg, the dosage was increased by 300 mg every 3 days so that a maximum of 1800 mg/day was reached in 13 days. This drug was combined with 300 mg/day of vitamin B_6 and was administered for as long as the blood picture permitted. Evaluation of histological findings in 14 patients who had been treated for as long as 20 months (mean 14 months) showed improvement in nine, no change in three, and deterioration in two. Of the latter two patients, one had cirrhosis and the other had a very active, chronic aggressive hepatitis which evolved into complete cirrhosis with portal decompensation within 4 months. At biopsy, three patients showed chronic persistent hepatitis and two had only residual periportal infiltrates; these two patients had been treated unsuccessfully for 4 and 2 yr, resp., with 75 to 100 mg/day of azathioprin, at times in combination with prednisolone. One seriously ill patient developed agranulocytosis in a 3-day period, but had a remission after D-penicillamine was discontinued and intensive antibiotic therapy was administered for 14 days. Another patient developed threatening leukopenia after 6 months of therapy, but was able to continue D-penicillamine when the dose was reduced to 600 mg/day. Some patients noted reversible changes in their sense of taste and others temporarily lost it. These disorders were traced by electrogustometry to areas innervated by the glosso-pharyngeal nerve; areas innervated by the facial nerve remained unaffected. Trials of copper salt substitution are planned for these patients. The results indicate the relatively high efficiency of D-pencillamine, and that intermittent leukopenia and granulocytopenia are not an absolute counterindication for this therapy.

6294 DIAGNOSTIC AND THERAPEUTIC ASPECTS OF CHRONIC AGGRESSIVE HEPATITIS.

(Ger.) Gronauer, G.; Mauersberger, H.; zu Dohna, P. (Villingen-Schwenningen Munic. Hosp., Germany). *Therapiewoche* 24(37):4001-4002, 1974.

In 12 patients with chronic aggressive hepatitis, confirmed by laparoscopy or liver biopsy, quantitative determination of immunoglobulins was useful in routine diagnosis. IgG values were generally increased the most, with smaller increases in IgA and IgM. If IgG concentrations were normal, only IgM concentrations were increased. Patients with antinuclear and anti-smooth-muscle antibodies were given azathioprin + prednisone (doses unspecified), while those in whom no organ-specific antibodies were detected received D-penicillamine and vitamin B_6 (doses unspecified). Patients were then followed for six months to six yr. Almost all of these patients had been unsuccessfully treated with prednisone alone. Distinct improvement or normalization of immunoglobulin fractions, transaminase activites, and liver size and consistency occurred in all cases. Clinical and laboratory findings normalized completely in one patient given azathioprin + prednisone, and no recurrence developed in a two-yr period. The results of treatment were better and improvement occurred more rapidly in patients given D-penicillamine and vitamin B_6. Two patients who were initially treated with azathioprin + prednisone and responded favorably had recurrences of hepatitis when they were given D-penicillamine and vitamin B_6 instead. Distinct improvement occurred a short time after these patients were again treated with azathioprin + prednisone. Treatment with D-penicillamine and vitamin B_6 was unsuccessful in a patient with chronic aggressive hepatitis and organ-specific antibodies. Normalization of transaminase values and in the liver size and consistency occurre shortly after a change to azathioprin and prednisone Therapy was consistently successful in the group of patients with chronic aggressive hepatitis and no organ-specific antibodies who were treated first with D-penicillamine and vitamin B_6.

6295 HEPATITIS-B ANTIGENAEMIA ASSOCIATED WITH ACTIVE CHRONIC HEPATITIS AND MESANGIOPROLIFERATIVE GLOMERULONEPHRITIS.

(E.) Stratta, P.; Camussi, G.; Ragni, R.; Vercellone, A. (Cattedra Nefol. Med., Univ. Turin, Italy). *Lancet* 2(7926): 179, 1975.

The occurrence of hepatitis-B antigenemia in a 33-yr old patient with active chronic hepatitis-associated mesangioproliferative glomerulonephritis is reported The patient was hospitalized with a 1-month history of increasing weakness, peripheral edema, and dark urine. His serum contained hepatitis-B surface antigen but not antibodies. Active chronic hepatitis wa diagnosed after examination of a liver biopsy specimen. Microhematuria, cylindruria, and unselective proteinuria were also found; and immunoglobulin G (IgG) was increased while serum-complement (C3 and C4) levels were below normal. Glomerular filtratio was 70 ml/min and urinary fibrin-degeneration products were seen. Light and electron microscopic examination of a percutaneous renal biopsy specimen showed mesangial deposits and proliferation; immunohistochemistry revealed segmentary subendothelial deposits of IgG and immunoglobulin M widespread and generalized mesangial immunoglobulin A deposits, positive segmentary subendothelial immunofluorescen of lqC and C4 complement deposits, and diffuse and generalized subendothelial mesangial deposits of C3 There was hepatitis-B antigen in the glomerular mesangium. The evidence suggested the involvement of a circulating immune complex in the pathogenesis of the disease. It is concluded that serum and glomerular hepatitis-B antigen should be sought in glomerulonephritis of all histological types.

6296 ELECTROPHORETIC INTRA-CUTANEOUS INTRODUCTION OF MAGNESIUM IN THE COMBINED TREATMENT OF CHRONIC LIVER DISEASE IN CHILDREN.

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

6311 CONTRIBUTION TO ALCOHOLIC HEPATITIS. *(Ger.)* Stotzner, H. (Carl Gustav Carus Med. Acad., Dresden, Germany). *Zentrabl. Allg. Pathol.* 119(1/2):27-32, 1975.

Microscope examinations were performed on frozen and paraffin-embedded sections of punch liver biopsies taken from 64 patients (54 men and ten women, aged 26-69 yr) who had histories of drinking alcohol (mean 86 g/day) for long periods (mean 9.6 ± 5.2 yr) but who had no evidence of biliary disease or right heart failure or a history of exposure to hepatotoxic agents. Of these 64 patients, 30 (22 men and eight women) had alcoholic hepatitis. This was defined as neutrophilic granulocytes constituting: (1) about 1/3 of inflammatory cells in at least one affected portal field, (2) about 1/3 of inflammatory cells in one large intralobular focus of inflammation and (3) at least 1/2 of the cells in three or more small foci of inflammation. Hepatocytic necrosis was found in all 64 biopsies and the extent of this necrosis was not appreciably different in patients with alcoholic hepatitis and those without it. Of the 30 biopsies from patients with alcoholic hepatitis, all displayed steatosis; 15 had hydropic swelling, 19 had alcoholic hyalin, 17 had edema of the portal fields and 21 had bile duct proliferation. Two of these histological features were identified in seven patients; three were seen in 11 patients, four were seen in six patients and five were seen in six patients. No significant difference was found between the daily alcohol consumption or the duration of alcohol ingestion in patients with alcoholic hepatitis and those without it.

6312 IMMUNOLOGIC REACTIVITY AND ALCOHOLIC LIVER DISEASE. *(E.)* Zetterman, R. K.; Leevy, C. M. (Coll. Med. Dent. New Jersey, Newark). *Bull. NY Acad. Med.* 51(4):533-544, 1975.

The investigation of cell-mediated immunologic reactivity by means of lymphocyte transformation and the production of migration-inhibition-factor (MIF) improves the diagnosis and therapeutic perspective in the alcoholic with liver disease. Reduced lymphocyte reactivity to the mitogen phytohemagglutin (PHA) is frequently observed in malnourished alcoholics with liver disease. This can be attributed to a reversible disease in the synthetic capacity of DNA which occurs as a result of liver injury, nutritional deficiency, or circulating antagonists. It is suggested that immunologic hyperreactivity to alcoholic hyaline may be of crucial importance in the transformation of alcoholic hepatitis to cirrhosis. In spite of a decrease in the total number of T cells and reduced responsiveness to PHA, alcoholic hyaline evokes an increase in migration inhibition factor. Supernatants of sensitized lymphocytes, stimulated with this material, produce an increase in the incorporation of proline into collagen. It is suggested that this actin-like protein may serve as a neoantigen and may thus stimulate antibody-forming cells of T lymphocytes to release biologically active products. Immunologic competence, reflected in lymphocyte response to PHA, increases in the alcoholic, with improvement of hepatic reserve induced by abstinence and correction of nutritional deficiencies. Immunologic hyperactivity with release of migration-inhibition factor and fibrogenic factor persists despite progressive deterioration of the liver and eventually leads to a vicious cycle. It is felt that drugs which suppress immunologic response and reduce fibrogenesis may be useful therapeutic adjuncts in selected alcoholics with progressive hepatic-cell destruction despite abstinence from alcohol and a good diet.

6313 ABNORMAL RENAL ACIDIFICATION IN ALCOHOLIC LIVER DISEASE. *(E.)* Oster, J. R.; Hotchkiss, J. L.; Carbon, M.; Vaamonde, C. A. (Miami VA Hosp., Fla.). *J. Lab. Clin. Med.* 85(6):987-1000, 1975.

Studies were undertaken to better define the incidence and characteristics of acidification abnormalities in alcohol-induced liver disease and to demonstrate the practicality of using a calcium chloride ($CaCl_2$) acid-loading test of short duration in patients in whom ammonium chloride (NH_4Cl) might precipitate hepatic encephalopathy. After ingestion of 150 mEq $CaCl_2$, urinary acidification was studied for 6 hr in 22 normokalemic patients with alcoholic liver disease of varying severity and in 7 control subjects during 10 studies. The degree of the induced acidosis was similar in both groups. Of the liver disease patients, 9 were unable to normally lower urine pH below 5.25 and these were compared with the 13 patients achieving lower pH and with controls. This defect was consistently produced. Titratable acid excretion was less in the 9 patients than in the other groups. The percentage contribution of ammonium to maximal net acid excretion was significantly higher in all patients with liver disease than in controls. None of the group of 9 patients had spontaneous metabolic acidosis, nor was there evidence of encephalopathy or of proximal renal tubular dysfunction. Sodium excretion was significantly lower in the group of 9 patients than in either of the other two groups. Sodium sulfate and sodium phosphate infused after acid-loading rapidly reduced urine pH into the appropriately acidic range in the 9 patients. Incomplete distal renal tubular acidosis was thus delineated in 41% of the patients with alcoholic liver disease by means of a simple, safe, and short acid-loading test. Although the mechanism of this renal tubular acidifying defect remains unknown, a low distal delivery of sodium may have been partially responsible by limiting the transtubular potential difference.

6314 CELL-MEDIATED IMMUNITY TO LIVER IN PATIENTS WITH ALCOHOLIC HEPATITIS. *(E.)* Mihas, A. A.; Bull, D. M.; Davidson, C. S. (Boston City Hosp., Mass.). *Lancet* 1(7913):951-953, 1975.

The possibility that cell-mediated immunity to liver tissue is altered in alcoholic hepatitis was studied. Mononuclear cell responses to liver extracts were studied by a migration-inhibition assay in 24 patients with alcoholic liver disease (15 with acute alcoholic hepatitis and 9 with 'stable' Laennec's cirrhosis); 8 with viral hepatitis; 11 chronic alcoholics without evidence of liver disease; and in 15 healthy controls. Patients with acute alcoholic hepatitis demonstrated liver-antigen-induced inhibition of migration (migration index, 0.58), while patients with cirrhosis, alcoholism, and acute viral hepatitis, as well as controls, did not demonstrate such a response (migration indices, 0.92, 0.90, 0.86, and 0.99, resp.). It is concluded that cell-mediated immunity to normal or damaged liver tissue may act to perpetuate alcoholic hepatitis and thereby contribute to the development of cirrhosis.

6315 CHANGES IN THE RATE OF ALCOHOL CATABOLISM INDUCED BY PHENOBARBITAL, CHRONIC ALCOHOLISM, AND FASTING IN MAN. *(Ger.)* Bode, J. C.; Bode, C.; Thiele, D. (Med. Clin., Univ. Marburg, Germany). *Verh. Dtsch. Ges. Inn. Med.* 80:484-487, 1974.

The effect of long fasts (36 hr) and fructose on blood alcohol levels was studied in normal subjects whose average daily alcohol consumption was less than 20 g. Controls were given infusions of 0.5 g/kg alcohol over a 45-min period and, after a 30-min equilibration period, blood samples were taken at 20 min intervals for 1 hr to determine alcohol concentrations. The rate at which blood alcohol levels decreased was 20-60% slower after a 36-hr than after a 12-hr fast. Infusions of fructose (0.8 g/kg/hr), given 2 hr after alcohol, stimulated decreases in blood alcohol levels of an average of 48% after a 12-hr fast and of 125% after a 36-hr fast. These findings suggest that decreased reoxidation of cytoplasmic NADH, rather than decreased alcohol dehydrogenase activity, is responsible for inhibiting alcohol oxidation. Administration of phenobarbital (300 mg/kg/day) for 6 days to these controls increased the rate of alcohol oxidation by an average of 51%, but values decreased significantly 2-3 days after discontinuation of the phenobarbital. This could be interpreted as indirect evidence for the existence of an alcohol-inducible microsomal ethanol-oxidizing system, but fructose-induced stimulation of alcohol oxidation was not significantly affected by administration of phenobarbital. This suggests that phenobarbital increases alcohol oxidation by a mechanism similar to that of fructose (increased NADH reoxidation). Studies performed on 13 alcoholic inpatients (average daily alcohol consumption of more than 100 g) showed that alcoholics metabolized alcohol more rapidly than controls (3.15 *versus* 2.51 mM/l). Values which were significantly above the normal range were found in only four of the 13 alcoholics who had abstained less than ten days. Fructose infusions caused little or no stimulation of alcohol oxidation in these four patients. This suggests that metabolic changes in the livers of chronic alcoholics cause an increase in the rate of alcohol metabolism *via* accelerated reoxidation of NADH.

6316 INHIBITORS OF LEUKOCYTE CHEMOTAXIS IN ALCOHOLIC LIVER DISEASE.

(E.) Van Epps, D. E.; Strickland, R. G.; Williams, R. C., Jr. (Univ. New Mexico, Sch. Med., Albuquerque, N. M.). *Am. J. Med.* 59(2):200-207, 1975.

The characteristics of serum chemotactic inhibitory activity were determined and its relation to alcoholic liver disease and infection was examined in a study of 42 patients (37 men and 5 women, aged 23-68 yr) with alcoholic liver disease. Chemotaxis experiments were performed by the Boyden technique and chemotaxis was determined visually by counting the average number of cells migrating through the membrane per high power field for polymorphonuclear leukocytes or cells per oil immersion field for monocytes. The patients were also tested for lymphocytotoxic antibodies, relative proportions or absolute numbers of peripheral blood T and B lymphocytes, and serum immunoglobulin levels. Twenty-one patients showed serum chemotactic inhibitory activity. It was not related to any single biochemical or histologic feature in the patients studied. The frequency of chemotactic inhibitory activity was greatest in those with active infection. Serial studies demonstrated that chemotactic inhibitory activity may be a transient phenomenon, associated with active alcoholic liver disease or appearance of infection. Nine of 15 patients showed skin test anergy; chemotactic inhibitory activity was present in eight of these nine patients. Serum immunoglobulin A (IgA) and G (IgG) concentrations were significantly higher in patients with chemotactic inhibitory activity. Sucrose density gradient centrifugation of serums showing chemotactic inhibitory activity yielded three peaks of inhibitory activity: two had sedimentation coefficients of 10.7S and 6.8S, and the third was approximately 3S. The two higher molecular weight inhibitors were predominant in the 50% ammonium sulfate precipitate. Immunoabsorption by anti-IgA but not by anti-IgG or IgM columns removed the ammonium sulfate precipitable chemotactic inhibitors. The appearance of chemotactic inhibitors in patients with alcoholic liver disease may have relevance to their apparent susceptibility to serious infections.

6317 PLASMA LEVELS AND EXCRETION OF ESTROGENS IN URINE IN CHRONIC LIVER DISEASE.

(E.) Pentikainen, P. J.; Pentikainen, L. A.; Azarnoff, D. L.; Dujovne, C. A. (Univ. Kansas Med. Cent., Kansas City, Kan.). *Gastroenterology* 69(1):20-27, 1975.

Plasma levels of nonconjugated esterone (E1), estradiol-17β (E2), and estriol (E3) and excretion of these estrogens in urine in conjugated and nonconjugated forms were measured by radioimmunoassay in 17 healthy males and 33 males with alcoholic liver disease. Total estrogens in urine were estimated after hydrolysis of the glucuronide and sulfate conjugates in hot acid. All samples were assayed in duplicate. Patients with liver disease had significantly elevated plasma levels of E1 (74.2 ± 8.0 SE *versus* 26.0 ± 1.7 pg/ml, $P < 0.001$), E2 (29.3 ± 2.2 *versus* 23.3 ± 2.0 pg/ml, $P = < 0.05$), and E3 (11.5 ± 1.9 *versus* 6.5 ± 0.7 pg/ml, $P < 0.01$). Excretion of total E1, E2, and E3 in urine was significantly increased in patients with liver disease. The increase was primarily in the nonconjugated fraction. Among those patients with chronic liver disease, the presence of ascites was associated with significantly higher plasma levels of E1 and excretion of larger amounts of E1 and E2 in urine. No differences were observed in the small number of patients with gynecomastia. The changes in plasma and urinary E1 and E2 values correlated directly with several liver function abnormalities, in particular with abnormal values for prothrombin time and plasma albumin levels. The increased plasma levels as well as the increased excretion of E1, E2, and E3 in urine observed in these patients are compatible with the explanation that they result from an increased rate of peripheral conversion of androgens.

6318 ALCOHOL AND DIETARY FACTORS IN CIRRHOSIS. AN EPIDEMIOLOGICAL STUDY OF 304 ALCOHOLIC PATIENTS.

(E.) Patek, A. J., Jr.; Toth, I. G.; Saunders, M. G.; Castro, G. A. M.; Engel, J. J. (VA Hosp., Boston, Mass.). *Arch. Intern. Med.* 135(8): 1053-1057, 1975.

Alcohol intakes and dietary habits of 304 alcoholic, hospitalized patients were evaluated to determine whether differences exist in the drinking habits and dietary backgrounds of alcoholic patients with and without cirrhosis. Histories of alcohol intake were obtained using standard questionnaires. Dietary histories over a 2-yr period were based on the recall method using a questionnaire for inquiry into ten food categories. There were 195 patients with hepatic cirrhosis, 40 precirrhotics and 69 noncirrhotics. In 85% to 94% of patients, excessive drinking began before the age of 30. Noncirrhotics were prone to drink less straight spirits than the other two groups combined, but the differences were not significant. More precirrhotics drank only spirits than did cirrhotics. Mean total daily calories ranged from 3200 to 3500, alcohol contributing 51% to 58%. The noncirrhotic group had a 13% higher intake of protein than the cirrhotic group and a 13% higher intake from other food sources. The precirrhotic groups was small, and the standard errors of its mean intakes were large so that it did not differ significantly from the other groups on statistical analysis. A familial incidence of alcoholism occurred in 60% of cirrhotics and in 58% of noncirrhotic alcoholics. The findings suggest that dietary factors may be involved in the pathogenesis of the disease.

Cirrhosis

6333 CHILDHOOD CIRRHOSIS ASSOCIATED WITH ALPHA-1-ANTITRYPSIN DEFICIENCY. A GENETIC, BIOCHEMICAL, AND MORPHOLOGIC STUDY. *(E.)* Asarian, J.; Archibald, R. W. R.; Lieberman, J. (Stanford Med. Cent., Calif.). *J. Pediatr.* 86(6):844-850, 1975.

Clinical and pathological data on a fatal case of juvenile cirrhosis due to homozygous α_1-antitrypsin deficiency followed over a 6-yr period, and comparisons of the phenotypic and biochemical findings in 27 relatives of the three-generation pedigree, are presented. At age 2 yr, 4 months, the proband (a girl) was hospitalized for evaluation of ascites. The liver and spleen were enlarged 3 cm below the costal margin. Serum transaminase, alkaline phosphatase, and LDH values were moderately elevated. Cholesterol concentration and serum ceruloplasmin were increased. At exploratory laparotomy the diffusely enlarged, firm nodular liver was biopsied: advanced cirrhosis of undetermined etiology was shown. Hepatosplenomegaly increased and a mild hyperbilirubinemia developed over the next 2 yr. By age 5 yr, examination showed spider angiomata, ascites, and a prominent venous pattern, with hepatosplenomegaly. At age 7 yr, 6 months she developed steatorrhea and massive ascites. Serum α_1-antitrypsin was less than 50 mg/dl, and a diagnosis of cirrhosis due to severe α_1-antitrypsin deficiency was made. She died at 8 yr, 5 months, of hepatic encephalopathy. A study of 27 relatives of the proband revealed 15 with heterozygous MZ phenotypes. Levels of circulating α_1-antitrypsin and trypsin-inhibiting capacity were shown to be unreliable in identifying the heterozygous state, protease inhibitor typing being necessary for definitive diagnosis. The morphologic evolution of the hepatic changes in this condition were studied, and the importance of the periodic acid-Schiff stain in identification of the characteristic cytoplasmic bodies is stressed.

6334 SODIUM SULFOBROMOPHTHALEIN KINETICS IN CIRRHOSIS OF THE LIVER BEFORE AND AFTER PORTACAVAL SHUNT. *(E.)* Cartel, G.; Benedetti, G.; Spine, G. P. (Dep. Surg. Pathol., Univ. Padua, Italy). *Am. J. Surg.* 130(7):47-50, 1975.

BSP kinetics in 36 patients (aged 17-65 yr) with liver cirrhosis and portal hypertension were investigated before and after portacaval shunt by the method of Barber-Riley *et al.* Side-to-side portacaval antastomosis was performed in 18 cases, end-to-side in 2, and splenorenal in the remaining 2 of the 22 patients who underwent operation. After i.v. injection of 5 mg/kg BSP, blood samples were taken from the opposite arm every 3 min for 20 min and thereafter every 5 min during the 30-120 min postinjection. In the 36 patients the percentage retention of BSP at 45 min was 29.95 ± 2.08; there was no overlap with the values for 39 healthy controls, in whom the upper limit of percentage retention was 3%. Preoperative BSP transfer rates, calculated from the plasma disappearance curves, differed significantly from control rates. Liver uptake of BSP and its transfer from liver to bile were grossly reduced and its transfer from liver back to plasma was augmented. In 15 patients 1 month after shunt, the liver uptake of BSP was 29.6% lower than preoperative values, whereas the transfer rate of BSP from liver to bile was unchanged. In 7 patients 1 yr after operation, the liver uptake of BSP was 28.3% lower and the transfer of BSP from liver to bile 29.9% lower than preoperative values. Further significant increases in BSP retention percentage occurred at 1 month and 1 yr. These results show that the increased percentage retention of BSP in patients with liver cirrhosis is accompanied by decreases in liver uptake of BSP and in transfer of BSP from liver to bile; transfer of BSP from liver to plasma is increased. One yr after operation, the deterioration of liver uptake of BSP ceases, while transfer of dye from liver to bile slightly deteriorates. Whether this deterioration is due to the operation or to a spontaneous evolution of cirrhosis could not be determined.

6335 EFFECT OF ORNITHINE ALPHA OXOGLUTARATE ON BRAIN METABOLISM IN PATIENTS WITH CHRONIC LIVER DISEASE. *(E.)* James, I. M.; Hamlyn, A. N.; Brant, P. C.; Hildrew, P. (R. Free Hosp., London, England). *J. Neurol. Neurosurg. Psychiatry* 38(3): 214-218, 1975.

The effect of ornithine α-oxoglutarate infusion on brain metabolism in 6 patients (4 men and 2 women, aged 24-70 yr) with chronic liver disease was studied with particular attention to glucose utilization. The patients had portal vein thrombosis (1); alcoholic cirrhosis (2); cryptogenic cirrhosis (2); and primary biliary cirrhosis (1). All exhibited only minimal neurological signs. Brain oxygen and glucose consumption were studied before and after i.v. infusion of ornithine α-oxoglutarate over a 15-min period. A further patient admitted in deep coma was also studied before and after 4-hr infusion with 60 g ornithine α-glutarate. Initial cerebral blood flow values ranged from 38-79 ml/100 g/min. There was no overall change in cerebral blood flow after infusion, but individually some changes were fairly substantial. Changes in $PaCO_2$ did not appear to have been the reason for these flow changes. Cerebral oxygen consumption increased significantly in 4 of the 6 patients, while cerebral glucose consumption decreased significantly in 5. After infusion in the patient with coma, cerebral blood flow and oxygen consumption increased and glucose consumption fell. These data confirm the finding of anaerobic glycolysis in patients with hepatic encephalopathy. In these patients, the biochemical disturbance of anaerobic glycolysis can be at least partially reversed with α-oxoglutarate administration, but the mechanism by which these changes are effected remains in doubt.

6336 COMPLICATIONS IN THE TREATMENT OF BLEEDING FROM ESOPHAGEAL VARICES WITH BALLOON TUBES. *(Ger.)* Brunswig, D.; Spech, H. J.; Heine, W. D. (Med. Clin., Univ. Wurzburg, Germany). *Therapiewoche* 24(39):4261-4262, 4264, 4267, 1974.

In comparison with the mortality (57%) resulting from bleeding esophageal varices in cirrhotics, severe, unavoidable complications associated with balloon tamponade are negligible. The most common complications are esophageal rupture, penetrating pressure ulcers, and aspiration during intubation. Fatal complications appear to be less frequent and bleeding is more often controlled when the Linton-Nachlas, rather than the Sengstaken-Blakemore, tube is used. Prospective studies are needed to determine whether selective, intra-arterial infusions of vasopressin are superior to balloon tamponade, particularly when extensive varices of the fundus are present. Although many complications can be avoided by the use of proper technique, trained personnel and intensive care are required to recognize and prevent untoward effects of tamponade. While tamponade can be a life-saving emergency measure in the treatment of bleeding esophageal varices, patients should be carefully evaluated for portacaval shunt surgery.

6337 PERIOD-AMPLITUDE ANALYSIS OF THE ELECTROENCEPHALOGRAM CORRELATED WITH LIVER FUNCTION IN PATIENTS WITH CIRRHOSIS OF THE LIVER. *(E.)*

Kardel, T.; Stigsby, B. (Gentofte Hosp., Univ. Copenhagen, Denmark). *Electroencephalograph. Clin. Neurophysiol.* 38(6):605-609, 1975.

Studies of the activity distribution of the electroencephalogram (EEG) by period-amplitude analysis were made in 40 patients with liver cirrhosis, with or without a surgical portacaval anastomosis, and in 25 controls. From the two parieto-occipital leads, 100 sec of EEG were examined. A quantitative determination of liver function was made in the patients by the galactose elimination capacity. A gradual slowing of the EEG was observed when passing from controls to nonshunted cirrhotics and shunted cirrhotics. This was reflected by significant differences in the amount of activity in some of the frequency bands and by a decrease of the dominant EEG frequency. There was a statistically significant, although weak, positive correlation between the dominant EEG frequency and the galactose elimination capacity in the non-shunted patients and in both patient groups considered together; the correlation was not significant in the shunted patients considered alone. A similar shift to lower EEG frequencies was previously observed in patients with chronic renal failure. Thus, it is concluded that the slowing of the EEG in patients with cirrhosis of the liver is an unspecific expression of metabolic brain disturbance.

6338 CHANGES IN PLASMA VISCOSITY IN CHRONIC LIVER DISEASE. *(Ger.)*

Palme, G.; Kochen, M.; Leonhardt, H. (Steglitz Clin., Free Univ., Berlin, Germany). *Clin. Chim. Acta* 61(2):163-169, 1975.

Measurements of plasma viscosity were performed on fasting blood samples from 37 patients (20 men and 17 women, mean age 56 yr) with chronic hepatitis (six cases), chronic hepatitis evolving into cirrhosis (seven cases), active cirrhosis (six cases), and inactive cirrhosis (17 cases). Portal hypertension was diagnosed in 25 cases and esophageal varices in seven. On the basis of these findings, patients were classified into three groups. Decreased viscosity was found in patients with cirrhosis, severe portal hypertension, and esophageal varices. Viscosity was normal in patients with inactive cirrhosis without portal hypertension. Patients with active cirrhosis and chronic progressive hepatitis had increased viscosity. Increased plasma viscosity was associated with increased concentrations of IgG, while decreased viscosity was associated with low fibrinogen levels. Close correlations were also found between plasma viscosity and the activities of SGOT, SGPT, and GLDH. When 5 patients with chronic progressive hepatitis and increased IgG concentrations were treated with corticosteroids, the plasma and whole-blood viscosities decreased to normal values with a parallel decrease in SGOT activity as a manifestation of restored hepatocellular integrity and an improvement in the normotest (factors II, VII and X) as a manifestation of improved synthesis of liver-specific clotting factors. Further research is needed to determine whether blood viscosity values can be used as an indication for corticosteroid therapy in chronic liver disease.

6339 ALCOHOL AND LIVER CIRRHOSIS-A QUANTITATIVE PROBLEM? *(Ger.)*

Leibach, W. K. (Med. Clin., Univ. Bonn, Germany). *Therapiewoche* 24(51): 6025-6032, 1974.

The author's experience with a group of 526 male alcoholics, treated for 6 months as inpatients, showed that it was easier to ascertain the duration of alcohol abuse than to establish the daily consumption. The mean duration of alcohol abuse was 9.1 yr, but only 417 patients gave reliable information on their daily consumption; 186 (45%) reported amounts of 160 g or less, while 231 (55%) reported amounts above 160 g. The mean for the entire group was 180 g/day. On the basis of biopsy findings in 320 cases and clear-cut clinical diagnoses of cirrhosis in 14, patients were divided into four groups according to the duration of alcohol abuse. Since the daily consumption increased with increasing duration of abuse, the effect of these two factors could not be evaluated separately. Consequently, 216 patients with identical durations of abuse (about 8 yr) were subdivided into two groups with different daily consumptions. The age distribution and body weights were identical in these two groups. In patients consuming more than 160 g/day (mean 227 g), only 10% had completely normal histological findings, and precirrhotic changes were twice as common (33% *versus* 14%) as in patients consuming less than 160 g/day. While none of the patients in the second group had cirrhosis, cirrhosis was diagnosed in 14% of those consuming more than 160 g/day. Thus, the risk of developing alcoholic cirrhosis depends upon both the duration of alcohol abuse and the amount of alcohol consumed/day. In a group of 265 biopsied alcoholics, the average daily consumption was related to body weight and time in hours, and this was plotted against the extent of histological change. The resulting curve was almost a straight line. In this group of 265 biopsied alcoholics, the product of dose/kg body weight and the duration of abuse was calculated for each patient and ranked into 13 classes, and the incidence of cirrhosis and precirrhotic changes was determined for each class. Regression analysis demonstrated a highly significant correlation between the total dose of alcohol consumed/kg and the incidence of both cirrhosis and liver damage more severe than uncomplicated fatty liver.

6340 INSORPTION OF TRITIATED WATER IN CIRRHOSIS. *(Ger.)* Mertz, D. P.; Weiss, M. (Med. Polyclin., Univ. Freiburg, Germany). *Res. Exp. Med. (Berl.)* 165(1):9-18, 1975.

The insorption of tritiated water and its distribution volumes were studied in ten patients with cirrhosis (seven men and three women, aged 37-66 yr) and five normal controls after p.o. administration of 200 µCi of THO in an average of 100 ml water. Cirrhosis was alcoholic in etiology in four cases and was associated with mild diabetes mellitus in three cases and with hemochromatosis in one. Both blood and urine samples were taken before and blood samples were taken at 10-min intervals until 2 hr after the administration of THO. Then blood and urine samples were taken at hourly intervals between 3 and 24 hr after administration of THO. The time required for THO to reach its maximum concentration in the blood varied greatly (from 30-110 min) in cirrhotics and was not related to the volume of total body water or to the etiology of the cirrhosis. Although the time required to reach maximum THO concentrations was normal in three cirrhotics, it was significantly longer (mean 69.0 min) in cirrhotics than in controls (37.0 min). The volume of total body water related to weight was significantly greater (59.8%) in cirrhotics than in controls (52.8%). For the first 20 min after administration of THO, the rate at which THO was insorbed was the same in cirrhotics and controls. Values for this rate were significantly greater in cirrhotics after 40, 50, and 70 min. Although changes in fluid balance cannot be ruled out as a cause of slower insorption of THO in cirrhotics, it is suggested that changes in intestinal blood flow, tissue pressure, and colloid-osmotic pressure contribute to this abnormality.

6341 THE SYSTEMIC CIRCULATION IN PORTAL HYPERTENSION. *(Ger.)* Liehr, H.; Grun, M.; Thiel, H. (Med. Clin., Univ. Wurzburg, Germany). *Z. Gastroenterol.* 13:133-146, 1975.

Experimental and clinical studies were performed to determine whether the development of hyperdynamic circulation and disorders in volume regulation is a process associated with portacaval collaterals or with cirrhosis, and whether circulatory changes occurring in cirrhosis represent a mechanism compensating for changes in portal blood flow. In rats in which portal hypertension was gradually induced by occlusion of the portal vein with Ameroid rings, the cardiac output increased to a mean of 36.9 ml/min/100 g (control value was 6.3 ml/min), and the circulation time decreased to 2.8 sec (control value was 3.6 sec) with increasing shunt volume (64%). The blood volume was 7.5 ml/100 g in comparison with 6.3 ml/100 g for controls. These changes regressed with a decrease in the portacaval shunt volume caused by the formation of portahepatic anastomoses. Comparable values were obtained in rats with portacaval anastomoses 28 days after surgery. In 77 patients with cirrhosis, the cardiac output was 3.3 $l/min/m^2$ for those with few collaterals and 4.1 $l/min/m^2$ for those with pronounced collaterals. Similarly, a significant difference was found between the arm-ear time in patients with few collaterals (12.6 sec) and those with pronounced collaterals (10.2 sec). The blood volume increased significantly (from 74.2 ml/kg to 36.0 ml/kg) as the extent of portacaval collaterals increased. The ratio of blood flow to liver mass remained normal (shunt volume 64%), or decreased to 75% of the normal values (shunt volume 100%), as a result of increased cardiac output. It is concluded that hyperdynamic circulation and hypervolemia are only associated with a hemodynamically relevant portacaval collateral circulation and are independent of cirrhosis. These conditions develop independent of the portal pressure and can be considered to compensate for decreases in portal blood flow.

6342 VALUES OF LARGE DOSES OF PREDNISOLONE IN THE TREATMENT OF HEPATIC COMA IN CIRRHOTICS FOLLOWING SHUNT SURGERY. *(Ger.)* Paquet, K. J.; Figge, H.; Welte, D. (Surg. Clin., Univ. Bonn, Germany). *Therapiewoche* 24(42):4817-4820, 4823-4826, 1974.

Large doses of prednisolone were administered over a short period to 26 patients who developed any of the following indications after shunt surgery: (1) liver coma, no matter what the cause, (2) acute exacerbation of cirrhosis, or (3) increased fibrinolysis or disseminated intravascular clotting. In addition, prednisolone was given to patients with small livers and adequate functional reserves who required end-to-side portacaval shunts and to patients with decompensated liver function who underwent emergency surgery. Of these 26 patients, 16 had portacaval shunts and 10, distal splenorenal shunts; six underwent emergency surgery. Prednisolone was administered in doses of 100 mg/24 hr on days 1-4 postoperatively; 50 mg/24 hr on days 5-6; 100-300 mg/24 hr on days 7-8; and 10-100 mg/24 hr on days 9-14. Controls consisted of 50 patients who underwent shunt surgery and who, for the most part, developed no postoperative complications. Of the 26 prednisolone-treated patients, five died: the cause of death was liver coma with recurrent bleeding (2 cases), liver coma without recurrent bleeding (1), subphrenic abscess, local peritonitis, and septicopyemia following splenorenal shunt surgery (1), and pneumonia and heart failure (1). Among patients given large doses of prednisolone, SGOT and SGPT values which were significantly increased immediately after surgery normalized within 14-21 days; similar data were not available from the control group. The increase in bilirubin levels which occurred in the first two days after surgery was significantly higher among prednisolone-treated patients than among controls. Normalization of total protein and cholinesterase levels and clotting factors occurred within 10-14 days in prednisolone-treated patients. None of the prednisolone-treated patients developed side effects. Although these findings suggest that large doses of prednisolone may prevent liver coma from developing after shunt surgery, no definitive conclusions can be drawn because of the small number of patients treated and because of the many other therapeutic measures utilized to prevent liver failure (e.g., bed rest, high-carbohydrate diet, gastric suction, maintenance of fluid and electrolyte and acid-base balance, administration of antibiotics, albumin, plasma substitutes, aldosterone antagonists, lactulose).

6343 INCREASED FIBRINOGEN SYNTHESIS IN PORTAL HYPERTENSION.

(Ger.) Grun, M.; Liehr, H.; Thiel, H.; Brunswig, D.; Buchenau, D. (Med. Clin., Univ. Wurzburg, Germany). *Z. Gastroenterol.* 12(suppl.):409-410, 1974.

Portal hypertension, portacaval anastomoses, hypoxic atrophy of the liver, and hypervolemia with hypercirculatory syndrome were induced in rats by placing rings of expandable material around the portal vein. Six days after surgery the plasma fibrinogen level was still normal, but the mean blood volume had increased to 148% of control values, the plasma fibrogen pool to 154% of control values, and the rate of incorporation of ^{14}C-leucine into thrombin-precipitated plasma protein/g liver to 211% of control values. During normalization of the plasma volume by formation of portohepatic anastomoses (21 days after surgery), the rate at which ^{14}C-leucine was incorporated into thrombin-precipitated plasma protein decreased to 61% of the control values. Similar studies were performed on 28 patients with cirrhosis who were divided into three groups, depending upon the extent to which portacaval anastomoses had developed. In the group as a whole, plasma volume was increased. There was a positive correlation between this increase and the extent of the portacaval shunt volume. The hepatic volume decreased with increasing portacaval shunt volumes. Since the mean plasma fibrinogen level for the entire group was 223 ± 72 mg/100 ml, the plasma fibrinogen pool was increased to 8.23 ± 2.49 g. However, the extent of this increase differed in each of the three groups and was not related to hepatic volume. Thus, in both experimental animals and patients with cirrhosis the plasma fibrinogen pool is increased despite a decrease in the hepatic volume, suggesting that the rate of fibrinogen synthesis is increased. Therefore, the plasma fibrinogen pool is apparently regulated by the plasma fibrinogen level, even under pathological conditions.

6344 PIGMENTED CORNEAL RINGS IN A PATIENT WITH PRIMARY BILIARY CIRRHOSIS.

(E.) Fleming, C. R.; Dickson, E. R.; Hollenhorst, R. W.; Goldstein, N. P.; McCall, J. T.; Baggenstross, A. H. (Mayo Clin. Mayo Found., Rochester, Minn.). *Gastroenterology* 69(1):220-225, 1975.

A case report of a 54-yr-old woman with primary biliary cirrhosis in whom corneal rings similar to Kayser-Fleischer rings were detected by slit-lamp biomicroscopy is presented. Jaundiced serum was first noted in 1966. In 1969 a percutaneous needle biopsy of the liver showed marked inflammation of portal tracts with severe piecemeal necrosis, marked periportal and septal fibrosis, and a decrease in the number of interlobular bile ducts. The patient was treated with cholestyramine and fat-soluble vitamins. In September 1973 excretory urography confirmed a radioopaque renal stone, and the urine oxalate excretion was 60 mg/24 hr (normal <25 mg/24 hr). In May 1974 the patient showed high levels of serum ceruloplasmin, 97 mg/dl and repeated 88 mg/dl (normal 22.9-43.1); serum copper, 279 μg/dl (normal 75-145); urinary copper excretion, 221 μg (normal 15-49); and hepatic copper concentrations, 756 μg/g of dry weight of liver (normal 15-35). Needle biopsy of the liver revealed the cirrhotic stage of primary biliary cirrhosis with reduction in interlobular bile ducts and moderate atypical ductular proliferation. Results of ophthalmological examination were normal except for severe scleral icterus and 1.5-mm wide band of yellowish green pigmentation that extended around the entire periphery of each cornea and in the region of Descemet's membrane. The ring was denser peripherally and faded to normal cornea away from the limbus. The color and location of the pigment were like those of Kayser-Fleischer rings, but were of lesser density than is usual in patients with advanced Wilson's disease. Kayser-Fleischer rings, similar to those seen in this patient with primary biliary cirrhosis, have been observed in patients with early or minimal manifestations of Wilson's disease. Wilson's disease was excluded on the basis of the elevated serum ceruloplasmin and copper levels, the lack of neurological disease despite advanced liver disease, a negative family history and the typical clinical features of primary biliary cirrhosis. The patient was treated with a low-sodium diet, diuretics, cholestyramine and vitamin K.

6345 EFFECT OF LIVER FAILURE ON THE RESPONSE OF VENTILATION AND CEREBRAL CIRCULATION TO CARBON DIOXIDE IN MAN AND IN THE GOAT.

(E.) Stanley, N. N.; Salisbury, B. G.; McHenry, L. C., Jr.; Cherniack, N. S. (Univ. Pennsylvania Sch. Med., Philadelphia, Pa.). *Clin. Sci. Mol. Med.* 49(2): 157-169, 1975.

The acid base state of arterial blood and cerebrospinal fluid and the ventilatory response to inhaled CO_2 were evaluated in 12 patients with liver disease and the effect of liver failure in unanesthetized goat was determined. The pH, oxygen partial pressure (P_{O_2}) and CO_2 partial pressure (P_{CO_2}) in blood and cerebrospinal fluid of the patients were measured with appropriate electrodes, and arterial and cerebrospinal fluid bicarbonate concentrations were calculated from the measured P_{CO_2} and pH values. The ventilatory response to CO_2 was evaluated in both patients and animals by a modification of the rebreathing method. Liver failure was accompanied by a respiratory alkalosis in both the patients and in the goats. The P_{CO_2} was reduced and pH increased in the arterial blood; plasma bicarbonate concentrations were reduced in keeping with a partially compensated respiratory alkalosis. In the cerebrospinal fluid there was also a reduction in P_{CO_2}, a slight increase in pH, and a reduction in bicarbonate concentration. The slope of the ventilatory response to CO_2 was reduced when liver failure was severe, in patients and goats alike. There was a reduction in the extrapolated P_{CO_2} at zero ventilation, even when liver failure was mild. The mean cerebral blood flow fell by 30% after the onset of liver failure as compared with that in the control period, whereas cerebral vascular resistance increased by 40%. These changes were associated with hypocapnia, the mean arterial P_{CO_2} falling by nearly 10 mm Hg. The cerebral metabolic rate for O_2 fell by 22%. The dangers of hypercapnia in hepatic cirrhosis are confirmed by the fall in cerebral metabolic rate for O_2 induced by CO_2 breathing in the goats with liver failure. The possible clinical relevance of this adverse response to exogenous CO_2 is that cerebral function may be similarly impaired when a patient with liver failure is exposed to respiratory depressants.

6346 RESPONSE TO DOPAMINE HYDROCHLORIDE IN THE HEPATORENAL SYNDROME. *(E.)* Bennett, W. M.; Keeffe, E.; Melnyk, C.; Mahler, D.; Rosch, J.; Porter, G. A. (Univ. Oregon Med. Sch., Portland). *Arch. Intern. Med.* 135(7):964-971, 1975.

Seven patients with hepatorenal syndrome were studied before and after dopamine hydrochloride treatment (initially 2 μg/kg/min, increasing to 4-6 μg/kg/min intra-arterially and subsequently i.v.) to determine the effects of dopamine on the renal cortical vasculature and cortical blood flow rate. Five patients with decompensated cirrhosis of the liver without renal failure were also studied but were not given dopamine. Renal blood flow was measured by analysis of the washout curve of xenon 133 and selective arteriography was used to determine the status of the renal cortical vasculature. Renal pathological material was available from three cases at necropsy. Mean renal blood flow and flow rate through the cortical component were decreased in both groups of cirrhotic patients compared with a control group of normal transplant donors. Both cirrhotic groups also showed redistribution of blood from the cortex to juxtamedullary areas. After intra-arterial dopamine treatment in the hepatorenal patients, the cortical blood flow rate increased significantly, with insignificant increases in the mean renal blood flow and percent of total blood flow in component I. The antiographic findings paralleled the xenon Xe 133 curves in the hepatorenal patients and showed diffuse cortical vasospasm; in the five patients with no renal failure, the angiographic findings were within normal limits. Dopamine treatment improved the angiographic appearance of the renal cortical vasculature in the hepatorenal group. However, little improvement in renal function was noted after the i.v. dopamine infusions; urine osmolarity increased significantly and sodium excretion decreased significantly after i.v. dopamine, but changes in the urine volume and glomerular filtration rate were insignificant. Two patients survived the hepatorenal syndrome and left the hospital with normal renal function as an apparent result of dopamine treatment. No adverse reactions were noted as a result of the dopamine infusions. Renal histopathologic findings were normal in the three necropsy specimens. It is concluded that standard treatment involving symptomatic treatment of the liver disease, exclusion of the renal causes of azotemia, and intravascular volume repletion should be used in the treatment of hepatorenal syndrome.

6347 MASSIVE SPONTANEOUS PORTAL-SYSTEMIC SHUNTING WITHOUT VARICES. *(E.)* Wexler, M. J.; MacLean, L. D. (Dep. Surg., R. Victoria Hosp., Montreal, Canada). *Arch. Surg.* 110(8):995-1033, 1975.

Six patients, some with previously unsuspected liver disease or portal hypertension, with massive spontaneous portal-systemic shunts were identified by umbilical vein portal phlebography. In two patients, the shunt was between the splenic and left renal vein, while in another it was between the coronary and left renal veins. In two patients, a spontaneously reopened and patent umbilical vein served as a massive conduit anastomosing with the iliac system. In one patient, the shunt was via the inferior mesenteric vein to the hemorrhoidal plexus. None of these patients had esophageal varices and all but one were free of gastrointestinal bleeding. The spectrum of clinical manifestations varied greatly. Two totally asymptomatic patients were being investigated for splenomegaly and a third for epigastric pain; none was known to have liver disease. One patient had severe encophalopathy, while another with well-established asymptomatic liver disease since childhood was admitted with upper gastrointestinal bleeding of obscure cause. Five patients clearly demonstrated hepatofugal portal flow, while the sixth showed noticeable reduction of the portal fraction of total hepatic blood flow. All patients had small, shrunken livers, enlarged spleens, and demonstrated a striking absence of the plethora of collateral veins usually seen on venus portography in patients with portal hypertension. The spontaneous shunts resembled surgically constructed portal-systemic shunts in magnitude, and perhaps in volume of flow. Liver biopsies showed Laennec's cirrhosis in two patients, postnecrotic cirrhosis in two, and chronic aggressive hepatitis with cirrhosis in two. Spontaneous shunts may be more common than suspected in cirrhotics and may explain the lack of variceal hemorrhage in many patients.

6348 PORTAL AND SYSTEMIC EFFECTS OF SELECTIVE INFUSION OF VASOPRESSIN INTO THE SUPERIOR MESENTERIC ARTERY IN CIRRHOTIC PATIENTS. *(E.)* Millette, B.; Huet, P. M.; Lavoie, P.; Viallet, A. (Hospital Saint-Luc, Montreal, Canada). *Gastroenterology* 69(1):6-12, 1975.

The portal and systemic effects of a selective infusion of vasopressin into the superior mesenteric artery were evaluated in eight male cirrhotic patients with portal hypertension, who underwent umbilicoportal catheterization. Vasopressin was infused selectively into the superior mesenteric artery at a rate of 0.2 U/0.75 cc/min with a constant rate infusion pump for 40-60 min. Free portal venous pressure decreased significantly from 27.0 ± 1.4 mm Hg to 24.4 ± 1.4 mm Hg (9.6%). In all patients, portal oxygen pressure decreased significantly with a mean fall of 18.8%. Femoral arterial oxygen pressure decreased significantly (7.3%) while the mean femoral arterial blood pressure increased significantly (18.95) in all patients. Variable changes of the cardiac output were observed in the seven patients during the vasopressin infusion. In two patients, the cardiac output increased by 27 and 15%; in two patients, it was minimally decreased (1 and 8%), but in the other three patients it was markedly decreased by 35, 18 and 27%. It is concluded that selective infusion of vasopressin into the mesenteric circulation does not induce a marked decrease of the portal venous pressure in cirrhotic patients with portal hypertension undergoing umbilicoportal catheterization. In any controlled clinical trial, the risk of venous and/or arterial thrombosis, the decrease of portal oxygen pressure and possible systemic effects have to be considered in cirrhotic patients with ruptured varices.

6349 NEGATIVE INFLUENCES OF ASCITES ON THE CARDIAC FUNCTION OF CIRRHOTIC PATIENTS. *(E.)* Guazzi, M.; Polese, A.; Magrini, F.; Fiorentini, C.; Olivari, M. T. (Inst. Cardiovasc. Res., Milan, Italy). *Am. J. Med.* 59(2):165-170, 1975.

The negative influences of ascites on the cardiac function of 21 hospitalized men with Laennec's cirrhosis were investigated. Hemodynamic measurements were carried out with the patients in the fasting state, in the supine position and without premedication, at each of the following times: in the steady state and, resp., after removal of 500, 1000, 2000, 3000, 4000 and 5000 ml of ascitic fluid. The paracentesis was continued to remove as much fluid as could be obtained; in two patients it was 8000 ml. The hemodynamic pattern during paracentesis was characterized by no significant change in heart rate, systolic and diastolic arterial pressure, or pulmonary mean arterial and wedge pressures; progressive increase in cardiac output, stroke volume, stroke work, and mean rate of ejection of the right and left ventricle; increasing reduction in intra-abdominal pressure and in the inferior vena cava and right atrial pressures. Paracentesis was thus followed by circulatory variations which were primarily represented by improvement of right and left ventricular function, as clearly indicated by the significant increase in cardiac output exclusively due to an increment in stroke volume, by the rise in stroke work, and mean rate of systolic ejection of both sides of the heart. The improvement in cardiac function was associated with an increasing reduction in intra-abdominal, inferior vena cava and right atrial pressures. There was a direct relation between the decrease in systolic right atrial pressure and the increase in cardiac output at measured withdrawal of ascitic fluid. The average variations in systolic right atrial pressure were related to the average changes in right ventricular stroke work at measured drainage of ascites. The high caval and right atrial pressures along with the elevated abdominal pressure and the response to paracentesis suggest a mechanism in which tense ascites increase the hydrostatic intra-abdominal pressure acting on the diaphragm; this raises the intrapleural pressure, which, in turn, reduces the effective filling pressure of the heart and shifts the cardiac output curve to the right.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

6376 PROLONGED SECRETION OF LITHOGENIC BILE AFTER CHOLECYSTECTOMY. *(E.)* McDougall, R. M.; Walker, K.; Thurston, O. G. (Dep. Surg., Univ. Alberta, Edmonton, Canada). *Ann. Surg.* 182(2):150-153, 1975.

The possible secretion of a lithogenic bile following cholecystectomy for cholesterol gallstones was studied in eight patients 1.5 to 23 yr after cholecystectomy for presumed cholesterol gallsones. The cholesterol, lecithin, and bile acid levels in the hepatic bile of these subjects were compared with the levels in the gallbladder bile of 15 patients currently undergoing cholecystectomy for pure and mixed cholesterol gallstones in functional gallbladders. Bile was obtained by needle or T-tube aspiration of the common bile duct, duodenal catheter aspiration, or *via* gastrostomy tube. The hepatic bile samples for the subjects who had undergone cholecystectomy 1.5 to 23 yr previously were saturated or supersaturated with cholesterol in all cases, the mean lithogenic index for this group being 1.31. The bile in the 15 patients currently undergoing cholecystectomy was supersaturated with cholesterol in all but three cases, the mean lithogenic index being 1.41. The mean value of molar percent cholesterol in the current cholecystectomy group was 14.0, while that in the previous cholecystectomy group was 12.7. In the previous cholecystectomy group, bile supersaturated with cholesterol did not become less saturated with time. The data support the concept that, once begun, the production of a lithogenic bile by the liver is a lifelong phenomenon.

6377 STUDY OF CHOLELITHIASIS ASSOCIATED WITH CHRONIC PANCREATITIS. *(Fr.)* Callet, B.; Bernades, G.; Dupuy, R. (Beaujon Hosp., Clichy, France). *Arch. Fr. Mal. App. Dig.* 63(8):625-630, 1974.

Cholelithiasis was diagnosed in 17 (14 men and three women) of 101 patients with chronic pancreatitis. Chronic alcoholism (100 ml/day of pure alcohol for at least 2 yr) was present in 80 cases (75 men and five women) and pancreatic calcifications were detected in 71 cases. The diagnosis of cholelithiasis was made before that of chronic pancreatitis in three cases, simultaneously in ten cases and afterwards in four. No significant differences in sex, frequency of chronic alcoholism or acute pancreatitis, presence of pancreatic calcifications or associated cirrhosis or the course of chronic pancreatitis (regression, stabilization, exacerbation) were found between patients with chronic pancreatitis and those with chronic pancreatitis and cholelithiasis. Patients with cholelithiasis averaged 10.5 yr older at the onset of symptoms of chronic pancreatitis and 7.6 yr older at the diagnosis of chronic pancreatitis. Of the patients with cholelithiasis, 16 underwent surgery for cholecystitis (nine cases), prolonged cholestatic jaundice (six cases), or pancreatectomy (one case); the remaining patient died of cirrhosis and cholelithiasis was found at autopsy. It is concluded that the association between chronic pancreatitis and cholelithiasis is fortuitous and that cholelithiasis appears to play no role in the pathogenesis of chronic pancreatitis.

6378 TREATMENT OF PATIENTS WITH CHOLESTEROL GALLSTONES WITH CHENODEOXYCHOLIC ACID: CHANGES IN BILE ACID METABOLISM. *(Ger.)* Stiehl, A.; Raedsch, R.; Regula, M.; Kommerell, B. (Med. Clin., Univ. Heidelberg, Germany). *Inn. Med.* 2(1):13-18, 1975.

Chenodeoxycholic acid (CDC, 1.5 g/day) was used to treat ten patients, aged 35-74 yr, with cholesterol gallstones. Bile acid determinations were performed on fasting blood samples, 24-hr urine specimens and bile before and at various periods after institution of CDC therapy. CDC produced marked changes in the bile salt pool: significant increases occurred in CDC, ursodeoxycholic and lithocholic acids. While less than 5% of CDC, ursodeoxycholic, cholic and deoxycholic acids were present as the sulfate ester after administration of CDC, 67.4% of lithocholic acid was found in this form. Administration of CDC almost tripled serum concentrations of nonsulfated CDC and lithocholic acid, while serum levels of the sulfate esters of these acids remained almost the same. Only traces of ursodeoxycholic, deoxycholic, and cholic acids were found in the serum of these patients after CDC therapy. Administration of CDC significantly increased urinary excretion of the sulfate esters of CDC and lithocholic acids. In patients receiving CDC, serum concentrations of nonsulfated CDC, but not those of nonsulfated lithocholic acid, were increased by a test meal. These findings suggest that increases in serum bile acid concentrations may be due to a spillover of the bile acid pool. This spillover is increased by administration of a test meal. Since animal experiments have demonstrated that the sulfate ester of lithocholic acid is much less hepatotoxic than the acid itself, extensive sulfation of lithocholic acid in patients given CDC may be a mechanism protecting against liver injury.

6379 THERAPEUTIC PROPERTIES OF A CHOLERETIC AGENT, FLASTAPIOL, IN BILIARY DISEASE IN CHILDREN. *(Ukr.)* Shmorhun, S. S.; Zinchenko, T. V.; Maksiutina, N. P. (Kiev Inst. Postgrad. Med., USSR). *Pediatr. Akush. Ginekol.* 36(2):22-24, 1974.

Therapeutic application of flastapiol, a drug prepared from extracts of parsley fruit *(Petroselinum sativum)*, *Stachys recta* (a hedge-like perennial native to southeastern Europe and the Caucasus), sandwort (*Helichrusum arenarium*), pectin and sugar showed very good results in curing biliary disease in children. The drug was administered to patients aged 5-15 yr three times a day in the following doses: children 5-8, 0.5 g; children 9-12, 0.75 g; and children over 13, 1.0 g. Treatment lasted 14-26 days. Subjected to the study were 60 children: 36 with angiocholecystitis; 10 with cholecystitis; and 14 with angiocholitis. Treatment with flastapiol showed in general quick subjective improvement in the health of patients, a decrease in swelling of the inflamed liver, and the disappearence of abdominal pains. In addition, flastapiol showed very strong curing action on inflamed bile ducts. After treatment, the signs of inflammation in the duodenum of 51 (out of 60) children disappeared completely; five showed strong suppression; four, no effect. As a result of this clinical study, authors strongly recommend flastapiol, a drug with stimulating property on bile secretion of liver, as well as with spasmolytic, diuretic, and detoxicating properties for the treatment of biliary disease in children.

6380 KINETICS OF TRIGLYCERIDE METABOLISM DURING CHENODEOXYCHOLIC ACID THERAPY. *(Ger.)*

Begemann, F. (Eppendorf Univ. Hosp., Hamburg, Germany). *Z. Gastroenterol.* 13:314-317, 1975.

By using Farquhar's two-compartment model and precursor labeling with ^{14}C-palmitic acid, administered i.v., triglyceride kinetics were studied in five patients with cholelithiasis who were receiving 10-15 mg/kg of chenodeoxycholic acid. After 8 weeks of therapy, plasma triglyceride levels had decreased 10 to 20%. Studies performed before and after 8 weeks of drug therapy in three cases showed that decreased plasma triglyceride levels were associated with a decrease in the rate of plasma triglyceride turnover. This demonstrated that decreased plasma triglycerides were due primarily to a decrease in the rate at which endogenous triglycerides entered the plasma and not to an increase in peripheral catabolism. These findings could either be attributed to a decrease in endogenous triglyceride synthesis or to a decrease in plasma secretion of these triglycerides. Since the supply of triglyceride for plasma secretion increased in two cases and decreased in one, the results were inconclusive.

6381 CONGENITAL BILIARY ATRESIA. *(Ger.)*

Kleinteich, B.; Schickedanz, H. (Surg. Clin., Friedrich Schiller Univ., Jena, Germany). *Wiss. Z. Friedrich Schiller Univ. Jena, Math. Naturwiss. Reihe* 23(3/4):609-623, 1974.

In a 12-yr period, atresia of the extrahepatic biliary tract was successfully treated in only one of ten infants (six girls and four boys). Of these patients, seven had no symptoms for the first 2 weeks after birth, although acholic stools were present from birth in nine cases. The single exception was a girl whose stools became acholic 3 weeks after birth, but regained their normal color after 1 week. Laparotomy, performed at 6 weeks of age, showed atresia of the intrahepatic bile ducts and of the hepatic duct. However, since it was possible to pass a tube through the common bile duct, and contrast medium (injected into the gallbladder) passed through the bile duct and into the duodenum, accessory bile ducts were probably present. All patients eventually developed jaundice and hepatomegaly; only two had splenomegaly. Serum bilirubin levels, which ranged from 7.8 to 15.8 mg/100 ml, were not correlated with age, and direct bilirubin values were higher than indirect values in all cases. While no urobilinogen was detected in the urine in any of these infants, bilirubin was present in six cases. The WBC was increased (10,000 to 17,000 WBC/mm^3) in all cases. None of the patients had any evidence of syphilis, toxoplasmosis or listeriosis. At laparotomy, only two patients had operable forms, and choledochoduodenostomies were performed. One of these operated patients died 2 weeks after surgery, with liver failure due to progressive biliary cirrhosis. The other operated infant proved to have atresia of only a short segment of the common bile duct anterior to the papilla of Vater; all other extrahepatic bile ducts were normal. Bile and many small, pigmented gallstones were present in the common bile duct. The patient was discharged and remained in good condition 12 yr after surgery. Autopsies, performed in seven of the nine infants, showed that the cause of death was cirrhosis. Associated gastrointestinal anomalies were found in three patients, which consisted of hepatic, pancreatic, and intestinal malformations (one case), ileal stenosis (one case) and cystic fibrosis (one case).

6382 EMPHYSEMATOUS CHOLECYSTITIS: REPORT OF TWO CASES. *(Fr.)*

Samson, E.; Kibrite, A.; Roy, J. P. (L'Hôtel-Dieu de Quebec Hosp., Quebec City, Canada). *Can. J. Surg.* 18(2):192-196, 1975.

Two new cases of emphysematous cholecystitis, a relatively rare disorder, are reported and compared to other cases from world literature. Both patients were male; one of them was diabetic. Both men presented with abdominal pain of sudden onset, which was localized around the right hypochondrium, extending to the shoulders in one case and to the paraumbilical region in the other. Simple radiography of the abdomen demonstrated a gas-filled gallbladder which led to the diagnosis of emphysematous cholecystitis. Surgery, supported by antibiotics, revealed gas, stones and distended gallbladder in both patients, with necrosis of the vesicular wall in one, and onset of necrosis in the other. It is felt that none of the etiological theories proposed thus far can be accepted or rejected, due to very limited experience with emphysematous cholecystitis.

6383 EFFECTIVENESS AND LIMITATIONS OF INTRAVENOUS CHOLANGIOGRAPHY IN PANCREATIC DIAGNOSIS. *(Ger.)*

Frommhold, W.; Frommhold, H. (Inst. Med. Radiol., Univ. Tubingen, Germany). *Leber Magen Darm* 4(5):212-221, 1974.

Intravenous cholangiography can be used only to a very limited extent in the differential diagnosis of pancreatic disease because: (1) pancreatic diseases produce nonspecific morphological changes in the extrahepatic biliary tract and (2) good visualization of the common bile duct, which is necessary for the detection of these changes, cannot be obtained in 10 to 15% of i.v. cholangiograms. However, better analyses of the distal common bile duct can be obtained by infusing, rather than injecting, contrast medium and by using tomography and zonography. Zonography is also useful in detecting stones that do not produce shadows with conventional radiological techniques. Changes in the distal common bile duct are not necessarily specific for mechanical obstructions of the papilla since they can also be seen in diseases involving the head of the pancreas. Similarly, changes produced in the common bile duct by chronic pancreatitis or fibrosis of the head of the pancreas are also observed in pancreatic tumors or cholangiocarcinomas. However, these changes, when associated with pancreatic calcifications, suggest a diagnosis of chronic pancreatitis. Secondary changes in the common bile duct caused by acute pancreatitis are difficult to interpret. Pancreatic pseudocysts and retention cysts in the head of the pancreas occasionally displace and compress the common bile duct. Carcinomas of the head of the pancreas often displace the intrapancreatic part of the common bile duct in a lateral-convex manner, but similar changes also occur in pancreatitis. If a malignant tumor in the head of the pancreas produces stenosis in the upper biliary tract, cholangiocarcinomas and inflammatory processes, e.g. stenotic cholangiolitis, must be considered in a differential diagnosis. In low stenosis of the common bile duct with prestenotic dilatation of the proximal part, both papillary carcinoma and cicatricial, inflammatory changes in the head of the pancreas are possible diagnoses. In a few cases, i.v. cholangiography, in association with other conventional radiological techniques, e.g. barium swallow or hypotonic duodenography, may be helpful in the differential diagnosis of pancreatic disease, but in most cases it can only be regarded as a tool useful in preliminary diagnosis.

6384 GALLSTONES IN CHILDHOOD. *(Ger.)* Kock, H. J.; Reuter, G.; Noack, R. (Clin. Pediatr. Surg., Berlin, Germany). *Kinderaerztl. Prax.* 42(11):481-486, 1974.

Case reports are presented for six children (five girls and one boy, aged 9-14 yr) who were treated for cholelithiasis in a 17-yr period. Only two of these patients developed jaundice; one also had hepatomegaly and signs of parenchymal liver damage. Radiological findings were negative in three of the five children examined. Cholecystolithiasis alone was diagnosed in two cases. In one case it was associated with stenosis of the papilla of Vater and dilatation of the cystic and common bile ducts and in three cases with choledocholithiasis. In addition to cholecystectomy, two patients underwent choledochoduodenostomy and one underwent revision of the common bile duct. Gallstones, analyzed in five cases, consisted of cholesterol alone in four and mixed cholesterol-calcium oxalate stones in one.

6385 THE DISSOLUTION OF GALLSTONES WITH AND WITHOUT CHENODEOXYCHOLIC ACID. *(Ger.)* Mockel, G. (Hosp. TABEA, Hamburg-Blankenese, Germany). *Verh. Dtsch. Ges. Inn. Med.* 80:451-455, 1974.

For 9 months, a group of 25 patients (eight men and 17 women, aged 26-70 yr) with cholelithiasis were treated with chenodeoxycholic acid (average daily dose of 1 g). The following were considered contraindications for chenodeoxycholic acid therapy: (1) liver disease, wasting diseases, gastrointestinal disease with diarrhea, hematological disease, and impaired renal function; (2) pregnancy; and (3) patients in whom surgery was indicated. Almost no side effects occurred when this dose was used, while at higher dosages a few patients developed diarrhea. Diarrhea was alleviated by reducing the dosage to 0.75 to 1.0 g. Routine transaminase determinations showed no changes. Multiple gallstones, about the size of grains of rice, had disappeared from a 64-yr-old patient after 6 months of treatment with chenodeoxycholic acid. A 58-yr-old woman, who originally had six gallstones the size of cherries, had only two on a radiological examination performed after 8 months of treatment. In both cases, the gallstones had been dissolved without the development of any symptoms. Because gallstones tend to recur after they have dissolved, these patients continued to receive chenodeoxycholic acid.

6386 INCREASING PRODUCTION OF THE SULFATE ESTER OF LITHOCHOLIC ACID DURING CHENODEOXYCHOLIC ACID TREATMENT. *(Ger.)* Raedsch, R.; Stiehl, A. (Med. Clin., Univ. Heidelberg, Germany). *Verh. Dtsch. Ges. Inn. Med.* 80:447-448, 1974.

Since the concentrations of chenodeoxycholic acid (CDCA) and lithocholic acid (LCA) increase in the bile of patients undergoing treatment of cholelithiasis with CDCA and the concentrations of these bile acids might be hepatotoxic, studies were performed to determine whether the relative percentages of their sulfate esters increase and what serum and urinary bile acid concentrations are during CDCA therapy. In patients with cholesterol gallstones given 1.5 g/day of CDCA p.o., the nonsulfated fraction of serum CDCA increased significantly from 0.9 to 2.7 μg/ml, while only a slight increase occurred in the sulfated fraction of serum CDCA. The serum concentration of nonsulfated LCA increased significantly from 0.2 to 0.7 μg/ml, and the serum concentration of LCA sulfate increased significantly from 0.1 to 0.5 μg/ml. Since bile acid concentrations in the serum are subject to considerable circadian variations, their urinary excretion was measured in 24-hr urine samples. Little increase occurred in the urinary excretion of nonsulfated CDCA, but excretion of the sulfate ester of this bile acid increased significantly from 0.3 to 0.5 mg/24 hr. While urinary excretion of nonsulfated LCA underwent no appreciable change, the excretion of LCA sulfate increased from 0.4 to 0.6 mg/24 hr. Differences between blood concentrations and urinary excretion of the sulfate esters during CDCA therapy are attributed to their greater glomerular filtration or lower reabsorption in the proximal tubules than nonsulfated bile acids. Before and during CDCA therapy, the relative percentage of the sulfate ester of CDCA in the bile was 0.7%, while the relative percentage of the sulfate ester of LCA increased significantly from 3.8 to 37.7% after 8 weeks of therapy. Accumulation of LCA in the body is prevented by increased synthesis of its sulfate ester since the reabsorption of the sulfate ester is decreased in the intestine and its renal excretion is increased.

6387 VARIATIONS IN TOTAL BILE ACIDS AND THE ACTIVITIES OF SOME ENZYMES USED AS INDICATORS OF CHOLESTASIS IN THE BILE OF PATIENTS AFTER SURGERY. *(Ger.)* Massarrat, S.; Arendt, D.; Kordes, B.; Bauer, E.; Tucke, M. (Med. Clin., Univ. Marburg, Germany). *Verh. Dtsch. Ges. Inn. Med.* 80:530-533, 1974.

Starting 3 days after surgery, the rate of bile secretion was measured, and determinations of total bile acids and enzymes used as indicators of cholestasis (alkaline phosphatase, γ-glutamyltranspeptidase, and leucine aminopeptidase) were performed on bile samples taken from T-tubes in 11 patients with jaundice caused by cholelithiasis and in ten anicteric patients with cholelithiasis. Bile samples were taken at 7 and 11 a.m. and at 4 and 9 p.m. In both groups of patients, very close correlations were found between the secretion of bile acids/min and alkaline phosphatase activity/min and between the secretion of bile acids/min and the volume of bile secreted/min. Close correlations were also found between alkaline phosphatase and γ-glutamyltranspeptidase activities in both groups of patients. When enterohepatic circulation was reestablished by raising the T-tube, bile acid concentrations increased; bile acid concentrations and alkaline phosphatase and γ-glutamyltranspeptidase activities showed circadian variations. Bile acid concentrations and enzyme activities were highest at 7 and 11 a.m., decreased after lunch and, after a dinner at 6 p.m., increased again at 9 p.m. This suggests that bile acid concentrations and enzyme activities are subject to a circadian rhythm, but the effect of food ingestion cannot be ruled out. Changes in the alkaline phosphatase activity in the bile proved to be a better indication of changes in concentration than did the bile acid concentration.

6388 TURNOVER OF PLASMA CHOLESTEROL IN PATIENTS WITH CHOLESTEROL GALLSTONES.

(E.) Pedersen, L.; Arnfred, T.; Thaysen, E. H. (Dep. Med., Alborg Hosp. North, Denmark). *Acta Med. Scand.* 197(5):421-425, 1975.

Some kinetic parameters of cholesterol synthesis were measured in eight Caucasian patients with radiolucent gallstones (in well functioning gallbladders) and in two healthy controls. 1-α-2-α-^{3}H-cholesterol in ethanol solution (2 to 3 ml) was administered i.v. to all subjects. In three patients, the half-life of the radiocholesterol in the circulation was 10 min and the distribution of radioactivity in the lipoproteins was similar to that of cholesterol in healthy controls. Fasting plasma samples were obtained once or twice weekly from all subjects for 10 weeks following injection of the tracer, and the plasma cholesterol and plasma triglyceride levels were determined. In each subject some kinetic parameters were also calculated, including the input into and size of the cholesterol pool. The results were compared with those from 16 controls in a previous study. The statistical analysis failed to demonstrate significant differences between the gallstone patients and compiled controls in any of the parameters studied. The results indicate that patients with cholesterol gallstones have normal rates of input of cholesterol into the rapidly exchangeable cholesterol mass. It is suggested that the absorption of exogenous cholesterol may be decreased in gallstone patients.

6389 ADENOMYOMATOSIS OF THE GALLBLADDER.

(E.) Ram, M. D.; Midha, D. (Huron Road Hosp., Cleveland, Ohio). *Surgery* 78(2):224-229, 1975.

Adenomyomatosis of the gallbladder in 27 patients was reviewed to investigate the nature and treatment of the disease. Nine were diagnosed directly by radiography, 14 had gallstones, three had a nonvisualized gallbladder, and one case was discovered on surgery. Ages ranged from 21-72 yr with the highest incidence in the sixth and seventh decades of life. Of the 27, 25 were white and 17 were female. Clinical features included pain in the right hypochondrium, dyspepsia and fatty food intolerance. Duration of symptoms ranged from 3 months to 7 yr. Cholecystectomy was performed in each case. Two patients died of unrelated causes; 25 were asymptomatic six months later, and 20 who were followed up to a maximum of 7 yr remained asymptomatic. Radiology showed morphological changes best after a fatty meal. Contrast filled the dilated elements in the wall in the form of a saw-tooth edge along the margin. In the segmental variety of the disease, concentric narrowing was seen. Pathology showed gross thickening of the wall, confined to a definite area in the segmental and localized varieties. Histologically there was hyperplasia of the epithelial and muscular elements, intramural diverticulosis extending into the subserosal plane, and thickening of cell layers. It is concluded that the disease is probably due to a combination of proliferation and degeneration associated with functional dyskinesia, and is curable by cholecystectomy.

6390 EARLY FORMATION OF GALLSTONES FOLLOWING JEJUNOILEAL BYPASS FOR TREATMENT OF MORBID OBESITY.

(E.) Neshat, A. A.; Flye, M. W. (Duke Univ. Med. Cent., Durham, N.C.). *Am. Surg.* 41(8): 486-491, 1975.

A case of cholelithiasis and acute cholecystitis immediately following a jejunoileal bypass is presented. A 30-yr-old male presented with morbid obesity. All laboratory studies were within normal limits, except alkaline phosphatase levels 90 mμ/ml. Jejunoileal bypass was performed, at which time the gallbladder was found to be grossly normal without palpable calculi. Liver biopsy showed minimal fatty changes. He was discharged 2 weeks after surgery, but presented 6 days later with epigastric pain, nausea, and vomiting. He responded to bed rest, propantheline bromide and bland diet, and was discharged after 3 days. Five weeks after surgery he presented with abdominal pain and fatty food intolerance. Oral cholecystography revealed multiple small stones in the gallbladder. He responded to conservative treatment. Two weeks later he presented with right upper quadrant pain, nausea and vomiting. Laboratory tests showed uric acid (7.1 mg%), alkaline phosphatase (175 mμ/ml), and serum iron (62 mg%). Cholecystectomy was performed and multiple small, mushy gallstones were found. Analysis showed them to be composed of cholesterol and calcium bilirubinate. Liver biopsy showed severe fatty changes. It is suggested that typical postoperative metabolic changes, mostly of fat and protein malabsorption, potassium and calcium loss from diarrhea, and bile stasis from obesity affected the cholesterol to bile salt plus lecithin ratio in the bile, resulting in stone formation.

6391 CLINICOPATHOLOGICAL STUDIES ON THE RELATIONSHIP BETWEEN CHOLELITHIASIS AND CHRONIC PANCREATITIS.

(E.) Sato, T.; Saitoh, Y.; Noto, N.; Matsuno, S.; Tokutake, K. (Tohoku Univ. Sch. Med., Sendai, Japan). *Tohoku J. Exp. Med.* 113(2):97-111, 1974.

To clarify the relation between cholelithiasis and chronic pancreatitis, biopsies of the pancreas were obtained at laparotomy from 151 patients (69 men and 82 women, aged < 19 to > 80 yr) with cholelithiasis, and the secretin test of pancreatic exocrine function performed on 119 of these patients. Histologic findings were compared with those obtained in 31 patients with gastric cancer. Pancreatic exocrine function was normal in 89 (74.8%) of the 119 patients who underwent the secretin test, slightly disturbed in 25 (21.0%), moderately disturbed in 4 (3.4%), and markedly disturbed in 1 (0.8%). Of the 30 patients with disturbance, 17 had reduced maximum bicarbonate concentration, 10 had reduced volume of duodenal aspirate, and 9 had reduced total amylase output. Moderate or marked disturbance of pancreatic exocrine function was significantly more frequent in patients with bacteria in bile, dilation of the bile duct, and hypercholesterolemia. Results of the secretin test showed a significant correlation with the frequency and grade of histologic changes in the pancreas: while 75-78% of the patients with a normal test showed no histologic change, 4 of 5 with a moderate or marked disturbance in the secretin test had marked histologic changes. However, no significant difference in grade and frequency of histological change in the pancreas was demonstrated between patients with cholelithiasis and controls. In addition, histologic findings did not correlate with location and type of gallstones or with duration of symptoms. Only 5 (3%) of the 151 patients with cholelithiasis had chronic pancreatitis. The results support previous findings that the frequency of pancreatitis is not high in patients with cholethiasis even though there should be common constitutional factors existing between cholelithiasis and chronic pancreatitis.

6392 ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY FOLLOWING BILIARY SURGERY.

(Ger.) Stadelmann, O.; Kaufer, C.; Bogusch, G.; Miederer, S. E.; Sobbe, A.; Slotter, H.; Loffler, A. (Med. Polyclin., Univ. Bonn, Germany). *Leber Magen Darm* 4(5):201-211, 1974.

Endoscopic retrograde cholangiopancreatography (ERCP) was performed on 113 patients who had undergone biliary surgery and had postoperative upper abdominal discomfort, signs of cholestasis, or laboratory findings suggestive of biliary obstruction. ERCP was used only if i.v. cholangiography could not be performed or gave no clearcut diagnostic information. In cases in which at least one system of ducts was visualized, the biliary tract was visualized in 80% and the pancreatic tract in only 66%. In 52 cases, both pancreatic and biliary ducts were visualized; in 38, only the biliary ducts; and in 23, only the pancreatic ducts. Pathological changes were detected in 72 cases (64%); in the biliary tract in 61 of 90 cholangiograms and in 22 of the 75 pancreatograms; in 11 cases both systems were affected. The most commonly encountered changes in the biliary tract were papillary stenosis (39 cases), gallstones (11), and stenosis associated with gallstones (9). Hydatid disease of the liver was associated with prepapillary stenosis in one case, and Caroli's syndrome was associated with choledocholithiasis in another. Pancreatic disease, diagnosed in 15 cases, consisted of chronic pancreatitis in 11 patients and pancreatic carcinomas in four. The diameters of the common bile duct and hepatic ducts increased with age and in patients who had undergone cholecystectomy, providing that no pathological changes, particularly obstructions, were present. Some patients who had undergone choledochoduodenostomy developed blind loop syndrome and papillary stenosis. It is recommended that this procedure be combined with papillotomy.

6393 CHANGES IN BILE ACID METABOLISM DURING TREATMENT WITH CHENODEOXYCHOLIC ACID.

(Ger.) Stiehl, A. (Med. Clin., Univ. Heidelberg, Germany). *Z. Gastroenterol.* 13(suppl.):300-301, 1975.

In 10 patients with cholelithiasis, serum levels of nonsulfated chenodeoxycholic acid (CDCA) increased significantly from 0.9 μg/ml to 2.7 μg/ml during treatment with 1.5 g/day CDCA; CDCA sulfate levels remained essentially the same. After a test meal, serum CDCA values increased still further to 4.6 μg/ml, while CDCA sulfate only increased to 0.5 μg/ml. Serum lithocholic acid concentrations also increased significantly from 0.2 μg/ml before treatment to 0.7 μg/ml during treatment; the sulfate ester level of this acid also increased from 0.1 to 0.5 μg/ml. No appreciable changes occurred in levels of serum lithocholic acid or its sulfate after a test meal. Urinary excretion of CDCA increased only slightly (from 0.5 to 0.6 mg/24 hr) during CDCA treatment, while urinary excretion of its sulfate ester increased significantly (from 0.2 to 0.5 mg/24 hr). Similar results were obtained for urinary excretion of lithocholic acid and its sulfates. Bile acid determinations performed on bile from these patients revealed that during CDCA therapy the relative percentage of CDCA increased from 47% to 72%; ursodeoxycholic acid, from 2% to 17%; and lithocholic acid, from 1% to 3%. The relative percentage of cholic acid in their bile decreased from 41% to 4%, and that of deoxycholic acid, from 9% to 3%. All of these changes were significant. Before CDCA therapy, only 22.5% of lithocholic acid in the bile was present as the sulfate ester; during therapy this increased steadily to 67.5%. Since lithocholic acid is hepatotoxic, it is suggested that formation of its sulfate ester is a protective mechanism which leads to its rapid detoxification and excretion.

6394 SCANNING ELECTRON MICROSCOPE STUDIES OF THE MUCOSAL SURFACE IN THE GALLBLADDER IN CHOLECYSTITIS AND CHOLELITHIASIS.

(Ger.) Wagner, R.; Krieg, H. (Pathol. Inst., Johannes Gutenberg Univ., Mainz, Germany). *Z. Gastroenterol.* 13(2):348-355, 1975.

To determine the extent to which structural changes in the gallbladder mucosa contribute to lithogenesis, the mucosal surface of gallbladders removed from 11 women with cholecystitis was examined under the scanning electron microscope. Cholecystitis was associated with a polyp in one case and with cholelithiasis in 10. In the gallbladder from the patient with the polyp, the mucosal surface contained folds of various widths and depths which were located so close to one another that the crypts could not be seen; a few adhesions were observed between adjacent folds. The epithelium consisted of polygonal cells of various sizes. Microvilli of various heights were detected on the apical parts of these cells. In a few places, very small processes, called antennulae, projected from the protuberances on the distal ends of the microvilli. In gallbladders from seven patients with chronic cholecystitis, the mucosal relief was flattened so that the crypts could be seen. While some deep crypts measured 5-80 μ in diameter, shallow crypts were considerably wider. In addition to these changes, the mucosal surface in two patients with acute cholecystitis contained epithelial ulcerations containing fibrils of collagen and fibrin. There were many loose cells, mostly RBC, among the fibrils; some cells were deformed by the fibrin. Intracellular spaces were increased in width and some contained microvilli of different heights. Microliths were detected near isolated necrotic cells and the flattened epithelium, while larger stones were present in the crypts. In addition to a few pigment stones, stones of pure cholesterol were found. Older solitary stones of cholesterol were joined to form thick plates, while multiple, recently formed cholesterol stones consisted of thin, loosely joined plates. It is suggested that the microliths might produce cellular necrosis, resulting in an increase in the size of the stones and in the width of the crypts and causing flattening of the mucosal relief. However, it is not known whether this process is produced by cholecystitis or whether inflammation results from stone formation.

6395 SPONTANEOUS ENTEROBILIARY FISTULAS: SURGICAL EXPLORATION AND SURGICAL POLICY. EIGHT CASES.

(Fr.) Chartier, P. (no affil.) *Ouest Med.* 27(18):1673-1682, 1974.

To illustrate the causes of internal enterobiliary fistulas and surgical procedures for treating them, case reports are presented for eight patients (five women and three men, aged 41-82 yr). These patients constituted 4.3% of all 189 patients who underwent biliary surgery. A 63-yr-old man with a cholecystoduodenal fistula and a gallstone obstructing his duodenum was treated by cholecystectomy and duodenal suture, as was a 68-yr-old woman who had a cholecystoduodenal fistula associated with a sclerotic, atrophic gallbladder. A cholecystoduodenal fistula associated with a duodenal ulcer in a 41-yr-old man was treated by a Péan-type gastrectomy, cholecystectomy, and insertion of a Kehr drain. A 66-yr-old man with a choledochoduodenal fistula, who had undergone two operations for peptic ulcer complications, was treated by gastrectomy, a Y-shaped enterobiliary anastomosis, and Finsterer's gastrojejunostomy. A cholecystocholedochal fistula, associated with gallstones in the gallbladder, common bile duct, and liver in a 82-yr-old woman, was treated by cholecystectomy, choledochotomy, and choledochoduodenal anastomosis. A 79-yr-old woman who had a duodenocholedochal fistula, a duodenal diverticulum, cholangitis, and cancer with partial obstruction of the transverse colon underwent cholecystectomy, resection of the duodenal diverticulum, a Y-shaped enterobiliary anastomosis, and segmental colectomy. Fistulas between the gallbladder and hepatic duct in a 71-yr-old and a 69-yr-old woman, which were masked by cholelithiasis, were treated by cholecystectomy and a Y-shaped anastomosis between the hepatic duct and jejunum. All patients except the one with cancer of the colon survived. Five patients had no complications and were discharged from the hospital 10-21 days after surgery. One patient was given anticoagulants after she developed myocardial ischemia 48 hr after surgery, and three received antibiotics.

6396 CONGENITAL CYSTS OF THE INTRAHEPATIC BILIARY TRACT (CAROLI'S DISEASE). *(Ger.)*

Siedek, M.; Kaufer, C.; Clemens, W.; Stadelmann, O.; Bucheler, E. (Surg. Clin., Univ. Bonn, Germany). *Leber Magen Darm* 4(5):242-246, 1974.

A 32-yr-old man, whose brother had chronic hepatitis, was hospitalized eight times in a 10-yr period for undiagnosed pain in the upper right abdomen. A cholecystectomy, performed for suspected cholecystitis, showed no evidence of stones in the gallbladder; a choledocholithotomy was performed at the same time. The biliary tract was not visualized radiologically. The following year, the patient was hospitalized for cholangitis and pancreatitis and was treated with antibiotics. The next year, he was hospitalized again for colic-like pain in the upper right abdomen. An infusion cholangiogram performed with tomography showed weak contrasting of dilated bile ducts in the liver and a dilated common bile duct with prepapillary stenosis and a suggestion of gallstones. No evidence of tumors or echinococcal cysts was found by radiological examination of the hepatic duct or by splenoportography. Some branches of the hepatic artery and portal vein were compressed, and the configuration of the left branch of the portal vein was atypical. Choledocholithotomy and transduodenal papillotomy were performed after removal of four prepapillary stones. A diagnosis of Caroli's disease was established by transpapillary visualization of multiple cysts in the intrahepatic bile ducts. Histological examination of a liver biopsy showed fibrosis associated with pericholangitis. *Klebsiella*, *Pseudomonas*, and enterococci were cultured from the bile. The patient was given antibiotics after surgery and recovered uneventfully.

6397 CARCINOMA OF THE DUODENAL PAPILLA: BYPASS, WHIPPLE'S PROCEDURE, OR PAPILLECTOMY?

(Ger.) Enderlin, F. (Cantonal Hosp., Basel, Switzerland). *Schweiz. Med. Wochenschr.* 105(18):592-595, 1975.

In a 20-yr period, surgery was performed on 41 patients, aged 47 to 80 yr (mean, 62 yr) with carcinomas of the duodenal papilla. The procedure employed was palliative in 16 cases (12 enterobiliary anastomoses and four biliary fistulas), although only three of these 16 patients had confirmed metastases. The surgical mortality was 30%, and the average survival time was only a few months; 2/3 of the patients died within 1 yr. Four of the 16 had undergone cholecystectomy 1 to 3 months before tumor surgery. Whipple's procedure was performed on 17 patients, four of whom had been previously cholecystectomized; five had confirmed lymph node metastases. In noncholecystectomized patients, the gallbladder was removed as a site of potential inflammation, as was the distal part of the stomach, to prevent the development of ulcers. Of these 17 patients, two underwent surgery within the last month and three are alive 2.7, 5, and 22 yr after surgery. Tumors or metastases resulted in death in 12 cases, but eight of these survived more than 1 yr and three survived more than 2 yr. Papillectomies were performed on three patients with localized tumors and on five elderly patients. Two patients are apparently tumor-free after 4 yr, but two others have died of recurrences.

6398 ULTRASOUND TOMOGRAPHY: A SAFE METHOD FOR THE DIAGNOSIS OF CONGENITAL CYSTS OF THE COMMON BILE DUCT.

(Ger.) Weitzel, D.; Beck, J. D. (Pediatr. Clin., Univ. Mainz, Germany). *Klin. Paediatr.* 186(5):460-464, 1974.

A 5-yr-old girl was suspected of having chronic aggressive hepatitis because of a history, dating back to infancy, of episodes of diarrhea and vomiting which recurred at 4 to 10 week intervals and were accompanied by colic-like pain, slimy, light yellow stools and dark urine. She failed to respond to diet therapy, fructose infusions, and fluocortolone administered over a 3-month period. At admission she had jaundice, hepatomegaly, an increased RBC sedimentation rate, and increased WBC, SGOT, SGPT, bilirubin and α_2-globulin values. Indirect evidence of a space-occupying lesion in the pancreas or hepatic portal was obtained by a barium swallow examination, and a liver scan indicated the lesion was located in the right lower lobe. Findings from celiac angiography were consistent with an avascular tumor, and larparoscopy revealed a full gallbladder, massive dilatation of the common bile duct, and an enlarged liver with gross signs of biliary cirrhosis. Findings obtained with ultrasound tomography B were interpreted as excessive dilatation of the bile duct, enlargement of the gallbladder, enlargement of the intrahepatic bile ducts, and diffuse connective tissue proliferation in the liver. At surgery, the common bile duct was about 12 to 15 cm long and 3-5 cm in diameter and, on gross examination, was closed near the papilla. When this bile duct was punctured, 140 ml of bile were obtained. A choledochoduodenostomy was performed and the patient recovered uneventfully. Pathological laboratory findings normalized within a few weeks. Examination of a biopsy taken from the liver at surgery showed biliary cirrhosis. Ultrasound tomography is recommended as the only technique for diagnosing biliary cysts since it shows the space-occupying lesion and its location directly and confirms the fluid nature of the cyst.

6399 PRIMARY CARCINOMA OF THE GALLBLADDER: REPORT ON 36 CASES.

(Ger.) Von Schoning, G.; Anders, A.; Pludra, J. E. (Steglitz Clin., Free Univ., Berlin, Germany). *Chirurg* 46(1):40-46, 1975.

Primary carcinoma of the gallbladder was diagnosed in 36 of 1228 operations on the biliary tract performed in a 4-yr period (2.9%). These 36 patients consisted of 34 women and two men; all but one were over 50 yr old (mean age 69.2 yr). The most common symptom was pain, present in all but four of these patients; upper abdominal tumors or hepatomegaly were found on palpation in 25 cases. None of the laboratory tests performed (alkaline phosphatase, transaminase, hemoglobin, SBC, RBC sedimentation rate and bilirubin) were diagnostic for carcinoma of the gallbladder. Cholangiography was of little value, because the biliary tract was not visualized in jaundiced patients. Barium swallow only suggested the presence of tumors in the biliary tract if the tumor compressed the duodenum and stomach or if a biliary fistula was present. The diagnosis was not established at surgery in six cases, although an experienced pathologist was able to diagnose carcinoma in three of these cases by gross examination of the tissues removed at surgery. This suggests that frozen sections should be examined during surgery. Histological examinations showed that 27 of the 36 patients had adenocarcinomas; these included seven solid undifferentiated and seven mucus-secreting adenocarcinomas. Of three squamous cell carcinomas, two were keratinized. Undifferentiated solid carcinomas were found in three patients, and no histological information was available for three others. Although surgery is generally palliative (carcinomas of the gallbladder soon invade the liver and then the regional lymph nodes), five patients were asymptomatic for more than 12 months after surgery; one patient had a localized carcinoma of the gallbladder and it was possible to remove regional metastases in the other four cases.

6400 ENDOSCOPIC PAPILLOTOMY. EXPERIMENTAL STUDIES AND INITIAL CLINICAL EXPERIENCE.

(E.) Koch, H.; Classen, M.; Schaffner, O.; Demling, L. (Med. Dep., Univ. Erlangen-Nuremberg, Erlangen, Germany). *Scand. J. Gastroenterol.* 10(4):441-444, 1975.

Experimental studies and initial clinical experience in the use of a high-frequency diathermy probe to perform endoscopic papillotomies are reported. Satisfactory papillotomies were performed on 11 dogs, and on the basis of these results endoscopic papillotomies were carried out in 23 patients. Indications for endoscopic papillotomy included common bile duct calculi in 11 high-risk patients; common bile duct calculi overlooked during bile duct surgery in six patients; recurrent calculi after previous cholecystectomy in three cases; and circumscribed papillary stenosis in three patients. For endoscopic papillotomy, the following procedure was adopted: retrograde contrast medium visualization of the common bile duct, possibly also of the main pancreatic duct; introduction of the papillotomy probe; accurate radiological check of the position of the papillotomy probe; and papillotomy. Papillotomy was successful in all 23 cases. At the endoscopic and radiologic follow-up examination carried out three to five days after papilotomy, no further stones were demonstrable in the bile duct in nine cases, indicating they had been passed spontaneously. In ten cases, the calculi had to be extracted using the Dormia basket or a wire loop. One patient had an attack of pancreatitis and the common bile duct had to be removed surgically. Further complications, in particular the occurrence of massive postoperative bleeding, were not observed. The clinical results show that endoscopic papillotomy carried out with the aid of a high-frequency diathermy probe is feasible in human patients and makes it possible to remove calculi in the common bile duct without opening the abdomen.

6401 DRUG ABSORPTION IN PATIENTS WITH T-TUBE AFTER CHOLECYSTECTOMY.

(E.) Aukee, S.; Venho, V. M. K.; Jussila, J.; Karjalainen, P. (Univ. Cent. Hosp., Kuopio, Finland). *Ann. Clin. Res.* 7(1):42-46, 1975.

The influence of bile flow on gastrointestinal absorption of tetracycline, doxycycline, sulfamethazine, and cycloserine was studied in 13 volunteer patients with T-tubes in their main bile ducts following biliary surgery. Gastroduodenal tubes were installed 1 week after cholecystectomy, and hepatic function and bile flow were evaluated following the i.v. administration of 10 µCi of I^{131} rose-bengal. In one group of patients, 1 g of tetracycline hydrochloride aqueous suspension was then administered via the gastroduodenal tube; the tube was rinsed with water and 0.75 g of sulfamethazine was given as an aqueous solution. In the other group of patients, 0.2 g of doxycycline and 0.5 g of cycloserine were given p.o. In both groups, blood samples were taken before and at various intervals after drug administration. The experiments were repeated three days later, after the T-tube was closed. Liver function did not vary in either group whether the T-tube was open or closed. About 80% of the radioactive tracer was recovered from the bile when the T-tube was open, so most of the bile was diverted outside the intestinal tract. Up to 4 hr after administration, the serum tetracycline levels were lower when the T-tube was open than when it was closed. In one patient, the serum levels were decreased to such an extent that therapeutic serum tetracycline levels could not be achieved. The serum doxycycline levels were fairly high and bile flow did not have any effect on doxycycline absorption. The 24-hr biliary excretion of this drug was only about 15% of the urinary excretion. The absorption of sulfamethazine and cycloserine was not affected by the presence or absence of bile. The results indicate that enterohepatic circulation of doxycycline is not important for the maintenance of its serum levels, that intact bile flow is not essential for the absorption of sulfadimidine, and that with the doses currently used, therapeutic serum levels of tetracycline can be expected even in cases of diminished bile flow.

6402 THE REMOVAL OF RETAINED GALLSTONES FROM THE COMMON BILE DUCT: EXPERIENCE WITH SODIUM CHOLATE INFUSION AND THE BURHENNE CATHETER.

(E.) Britton, D. C.; Gill, B. S.; Taylor, R. M. R.; James, O. (R. Victoria Infirm., Newcastle upon Tyne, England). *Br. J. Surg.* 62(7):520-523, 1975.

The use of cholic acid and the Burhenne catheter in the management of gallstones retained in the common bile duct following biliary surgery was studied in nine patients 3-16 weeks after cholecystectomy and exploration of the common bile duct. In four patients, an i.v. catheter was passed down through the T tube to the junction and a sodium cholate solution was infused at a rate of 30 ml/hr for up to 12 days. In two other subjects the T tube was removed and the Burhenne catheter was passed down the T tube tract and manipulated into the common bile duct; the stones were trapped in a Dormia basket passed through the catheter and removed. Three additional subjects received sodium cholate infusion followed by instrumentation with a Burhenne catheter. Liver function tests and estimations of serum electrolytes and serum amylase were performed daily and cholangiograms were performed at intervals of 4 days. Four of the seven patients treated with cholic acid infusion showed disappearance of the gallstones within 8-12 days. In another subject, one stone disappeared during infusion and a second stone was successfully removed with a Burhenne catheter; in one other patient, sodium cholate infusion was ineffective, but the stone was removed by instrumentation. Two attempts at using a Burhenne catheter alone failed as did one attempt at instrumentation following ineffective sodium cholate treatment. All patients treated with sodium cholate developed diarrhea, often quite severe, and became nauseated and anorexic and vomited intermittently. Biliary peritonitis occurred after use of a Burhenne catheter in one patient and after removal of the T tube in a patient treated with sodium cholate. The successful use of the Burhenne catheter appears to require considerable practice and expertise, and should perhaps be reserved for centers with particular interest in its use.

6403 BILIARY AND URINARY CALCULI: PATHOGENESIS FOLLOWING SMALL BOWEL BYPASS FOR OBESITY.

(E.) Wise, L.; Stein, T. (Washington Univ. Sch. Med., St. Louis, Mo.). *Arch. Surg.* 110(8):1043-1047, 1975.

The pathogenesis of biliary and urinary calculi following small intestine bypass procedures was studied in 93 patients who had undergone jejunoileal bypass procedures for massive exogenous obesity. In each case, 35 cm of the proximal jejunum was anastomosed end-to-end with the terminal portion of the ileum. I.v. cholecystokinin was administered to the fasted subjects and bile was collected in a double-lumen gastroduodenal tube. (^{14}C)Cholate (10 µCi) and (^{14}C)chenodeoxycholate (10 µCi) were then administered i.v. and bile-rich duodenal fluid was collected 3, 24, 48, and 72 hr later. Bile salt synthesis and the bile salt glycine/taurine ratio were determined. Within a mean follow-up period of 17.6 mon, three of the 93 patients developed urinary calculi, four developed gallstones, and one developed both urinary calculi and gallstones. Four of the gallstone patients were asymptomatic and one complained of vague upper abdominal pain, while all of those with urinary stones were hospitalized with typical "ureteric colic." A significant postoperative increase in urinary oxalate excretion was correlated with a significant decrease in urinary volume. The 24-hr preoperative urinary oxalate excretion in the four patients who developed urinary calculi was less than 20 mg, while the postoperative values were 94, 107, 51, and 52 mg/24 hr. The stones in these cases were all calcium oxalate calculi and all patients passed them spontaneously or with the help of retrograde catheter manipulation. The rate of bile salt synthesis increased significantly from 1.6 g/day preoperatively to 4.9 g/day postoperatively, and the bile salt glycine-taurine ratio increased significantly from 4.6 to 6.8. It is suggested that the postbypass increase in the biliary glycine/taurine ratio, with its consequent decrease in the zeta potential of the bile micelles, was at least partially responsible for the increased incidence of cholelithiasis. The pathogenic basis for the increased incidence of urinary calculi was hyperoxaluria, which was probably related to the increased bile salt and glycine synthesis.

6404 THE RATE OF DRUG BIOTRANSFORMATION REACTIONS AND CELLULAR VIABILITY IN THE LIVERS OF PATIENTS WITH BILIARY DISEASES. *(E.)* Hietanen, E.; Auranen, A.; Savvakis, C. (Dep. Physiol. Surg., Univ. Turku, Finland). *Acta Hepatogastroenterol. (Stuttg.)* 22(3):170-175, 1975.

The determine how biliary diseases affect hepatic drug metabolism and cellular viability, the cytochrome P-450 concentration, rate of o-aminophenylglucuronide synthesis, and oxygen consumption were measured in liver slices from 62 female patients with uncomplicated cholelithiasis, chronic cholecystitis, choledocholithiasis without bile duct obstruction, or bile duct obstruction and jaundice. The hepatic cytochrome P-450 concentration was highest in the patients with uncomplicated cholelithiasis, slightly decreased in those with chronic cholecystitis, and decreased by about 20% (compared with the uncomplicated cholelithiasis patients) in the patients with bile duct stones without jaundice. The rate of o-aminophenylglucuronide synthesis was similar in the patients with gallstones, chronic cholecystitis, and choledocholithiasis without jaundice; this rate was significantly higher in the patients with obstructive icterus than in the patients with chronic cholecystitis and was significantly higher than in those with gallstones or choledocholithiasis without obstruction. The oxygen consumption by the liver slices from the patients with obstructive jaundice was higher than that by the liver slices from the other groups. The formation of carbon dioxide did not differ among the four groups. It is suggested that the enhanced rate of glycuronidation was caused by the endogenous induction of increased bilirubin levels or by the accumulation of bile acids in the liver cells. The data suggest that drug hydroxylation and glucuronidation activities are under separate control mechanisms.

6405 THE EFFECT OF SODIUM BENZOATE AND TAUROCHOLIC ACID FEEDING ON HUMAN BILE COMPOSITION. *(E.)* Dennis, C.; Gardner, B.; Patti, J.; Chenouda, M. (Downstate Med. Cent., State Univ. New York, Brooklyn, N. Y.). *Proc. Soc. Exp. Biol. Med.* 148(3):602-605, 1975.

The effect of sodium benzoate and taurocholic acid feeding on bile composition was investigated in four patients who had cholecystectomy for cholesterol gallstones and common bile duct exploration with the insertion of a Baldwin T-tube. To determine if the glycine/taurine conjugation ratio could be reversed under acute conditions, the patients were fed sodium benzoate alone (6 g/day) for two or three days and then in combination with taurocholic acid (3 g/day) for three days. No significant changes were noted in serum alkaline phosphatase, bilirubin or glutamic-oxalacetic transaminase levels during the experiment. The benzoate was incapable of significantly lowering the glycine conjugates in the bile. Taurocholic acid significantly increased the concentration of taurine conjugates and markedly altered the glycine/taurine conjugation ratio. The only consistent results were the increase in taurine conjugates after feeding taurocholic acid. Total bile acids were significantly increased in all patients with a marked fall in glycine/taurine conjugation ratio. A proportional increase in biliary phospholipids and cholesterol was also demonstrated. There was no consistent change in the ratio of cholate to chenodeoxycholate concentration in any of the patients. Three patients demonstrated a slight fall in bile acid excretion which returned to normal due to an increase of taurine conjugated bile acid excretion. The results show that the usual glycine/taurine conjugation ratio of 3 or 4:1 consistently found in humans is the result of a relatively low taurine pool available for conjugation of bile acids and not due to preferential conjugation with glycine.

6476 UNUSUAL FEATURES AND COMPLICATIONS OF BEZOARS IN CHILDREN.

(E.) Harris, V. J.; Hanley, G. (Cook Cty. Child. Hosp., Chicago, Ill.). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 123(4): 742-745, 1975.

Detailed case histories are presented for three children with trichobezoars, and four others with bezoars are reported. The children (six girls and one boy) ranged in age from 15 months to 9 yr. A 3 x 3 cm mass was palpable in the left hypochondrium of the abdomen of the first case, a 4-yr-old girl, and another, 1.5 x 2 cm, was palpable in the left umbilical area. Both were smooth, nontender, superficial and mobile. A plain film demonstrated a radiopaque mass within the stomach, and segments were also seen in the jejunum, suggesting intussusception. The specimen (22 x 5 cm) was removed at surgery. Plain roentgenograms of the abdomen demonstrated a mass in the stomach in the second patient (a 15-month-old girl), as well as multiple small bowel fluid areas with an overall appearance suggestive of small bowel obstruction. At surgery a large comma-shaped trichobezoar (80 g) was removed from the stomach and multiple intussusceptions were reduced. An upper gastrointestinal series in the third case (a 6-yr-old girl) showed a large gastric bezoar, and perforations in the posterolateral and superomedial portions of the fundus of the stomach. At surgery a 300 g, foul-smelling trichobezoar was removed from the stomach. In addition, two perforations of the anterior wall of the stomach were found, and a large pelvic abscess was drained. The postoperative course was complicated by pneumonia, and the patient died. All seven patients seen had vomiting and abdominal pain as the most common presenting symptom, although anorexia, nausea, weakness, weight loss and constipation were also commonly seen. One patient unexpectedly passed a bezoar *via* the rectum after a 1-yr history of vomiting. Two of the children were mentally retarded, and the others were in need of psychiatric help.

6477 ASSESSMENT OF SIMPLE METHODS OF MEASURING INTESTINAL TRANSIT TIMES IN CHILDREN WITH GASTROENTERITIS.

(E.) Higgs, R. H.; Ellis-Pegler, R. B.; Lambert, H. P. (St. George's Hosp., London, England). *Gut* 16(6):458-461, 1975.

Intestinal transit times were measured in 11 children (aged 3-21 months) with gastroenteritis using carmine suspension and radioopaque pellets. The 2 methods gave widely divergent results. Sick children, often dehydrated and passing frequent fluid motions, were found by the carmine method to have rapid transit times consistent with the clinical picture (mean 2.5 hr). In contrast, the first pellets were seen over a range of 2-49 hr (mean 16.8 hr), similar to that found in controls without diarrhea. Other methods of measuring pellet transit times confirmed this anomaly. Clearly, the pellet method is unsuitable for use in gastroenteritis. It is suggested that the findings may be explained by sequestration of pellets in a particular area of the bowel such as stomach or cecum, or as an example of streaming of gut contents into solid and liquid phases. Pellets might thus be expected to travel in the slower solid phase. Carmine, as a solid suspension, is usually regarded as a solid phase marker, but the results of this study suggest that in acute gastroenteritis this substance travels with the liquid phase of the gut contents. No clear relation was noted between transit time, percentage dehydration, or the presence of reducing substance in the stool.

6478 SUCROSE IN ORAL THERAPY FOR CHOLERA AND RELATED DIARRHOEAS.

(E.) Nalin, D. R. (Cholera Res. Lab., Dacca, Bangladesh). *Lancet* 1(7922):1400-1402, 1975.

Sucrose was tested as a possible alternative to glucose in p.o. diarrhea therapy in 18 patients (17 men and 1 woman, aged 11-65 yr), including 13 with cholera. Each patient received p.o. sucrose plus electrolytes as a maintenance solution. All received tetracycline (250 mg, p.o., every 6 hr for 4 days) from the start of p.o. maintenance. Fifteen of the patients could be maintained using this solution, but 3 developed massive increases in net fluid losses and increases in plasma specific gravity, necessitating termination of p.o. therapy. It is suggested that these 3 patients may not have been able to hydrolyze sufficient sucrose to yield the amount of glucose needed for adequate absorption; this could account for the presence of sugar in the stool and could be attributed to the type of disaccharidase deficiency reported to occur during and after diarrheal episodes. Of 12 patients tested, all had significant concentrations of stool reducing sugar. These results using sucrose are in striking contrast to results with p.o. glucose-electrolyte solution. However, it is suggested that sucrose-electrolyte solution could be used successfully to treat most patients under emergency conditions, in which i.v. fluid supplies have to be conserved and glucose is not available.

6479 ACETYLSALICYLIC ACID AND GASTROINTESTINAL BLEEDING MEASUREMENT OF BLOOD LOSS USING A MODIFIED RADIOACTIVE CHROMIUM METHOD.

(E.) Arvidsson, B.; Magnusson, B.; Solvell, L.; Magnusson, A. (Radiat. Phys. Dep., Univ. Goteborg, Sweden). *Scand. J. Gastroenterol.* 10:115-160, 1975.

The fecal blood loss caused by a new acetylsalicylic acid preparation containing buffering substances was compared with the bleeding induced by plain acetylsalicylic acid tablets. Blood loss was quantified using a ^{51}Cr-labeling technique. Eighteen healthy male volunteers (aged 26-56 yr) were given one of two different salicylate preparations administered crossover in randomized order during two 7-day periods. One drug was a plain acetylsalicylic acid tablet containing 0.5 g acetylsalicylic acid. The other was a buffered tablet containing 0.5 g acetylsalicylic acid, 1.25 g sodium bicarbonate, and 0.5 g citric acid. The dosage was 1 g acetylsalicylic acid, 3 times/day from day 1-7. Two tablets were taken immediately before breakfast, two immediately before lunch, and two at 1 hr before dinner. The plain acetylsalicylate acid was swallowed whole with half a glass of water. The buffered preparation was first dissolved in the same amount of water. An interval of 3 weeks was allowed between the two different drugs. While receiving plain acetylsalicylic acid, 5 out of 18 subjects bled more than 10 ml daily. Three bled more than 20 ml daily. When receiving buffered acetylsalicylic acid, no subject bled 20 ml or more, and only 3 bled between 10 and 20 ml daily. Thus, a median daily blood loss of 4.6 ml during intake of plain acetylsalicylic acid was decreased to 2.0 ml during intake of the buffered preparation. The findings of this study confirm previous findings that increasing buffering capacity will successively decrease the amount of gastrointestinal blood loss. In this present study highly sensitive measuring equipment was used which made it possible to reduce the amount of ^{51}Cr from 1/3 to 1/10 of the previously used amounts.

6480 SERUM IgE IN EOSINOPHILIC GASTROENTERITIS. RESPONSE TO INTESTINAL CHALLENGE IN TWO CASES. *(E.)* Caldwell, J. H.; Tennenbaum, J. I.; Bronstein, H. A. (Ohio State Univ. Coll. Med., Columbus). *New Engl. J. Med.* 292(26):1388-1390, 1975.

Since serum levels of IgE have found wide application in the *in vitro* assessment of more common forms of allergy, e.g., ragweed sensitivity, a study of serum IgE was carried out in 2 patients with proved eosinophilic gastroenteritis. It was hoped to determine whether serum IgE in these patients correlated with historical evidence of food sensitivity and with results of intradermal testing. A 40-yr-old male had noticed gastrointestinal difficulty occurring within min after the ingestion of specific foods. His history revealed seasonal allergic rhinitis. There had been no correlation between upper-airway and digestive symptoms, and no relief of the latter by antihistamines which he took occasionally. Intradermal skin tests showed 2+ or greater reactions to grasses, ragweed, corn, oats, peas, barley, beef, egg, chicken, lamb, pork, and fish. Small bowel biopsy disclosed eosinophilia of the lamina propria and was otherwise normal. Since discharge he had been successfully treated with small doses of p.o. corticosteroids. Three yr later an assay of a serum sample for specific IgE antibodies by the radioallergosorbent test showed a 1+ score for fish, 2+ for ragweed, grass and corn, and 4+ for egg and wheat. In a second case, a 66-yr-old male was hospitalized because of eosinophilia and several weeks of postprandial diarrhea and abdominal distension. Gastroduodenal endoscopy was carried out, and biopsy showed dense infiltration of the pyloric and proximal duodenal mucosa with eosinophils and an otherwise normal mucosa. Intradermal tests for numerous inhalants and food allergies were negative. Skin tests for mumps and histoplasmin were positive at 48 hr. He was treated with low doses of oral corticosteroids with improvement for a period of 2 yr. Intestinal challenge studies caused the serum IgE levels in the former patient, already markedly elevated in the fasting state, to rise nearly 3-fold within the hr after challenge with food to which he was clinically sensitive. Challenge of the latter patient evoked no symptoms and no change in the normal base-line level of IgE. These data indicate that a mechanism other than classic immediate hypersensitivity was involved in the second patient's illness. In contrast, the first patient appeared to have true IgE-mediated food allergy.

6481 EARLY RECOVERY OF EXOCRINE PANCREATIC FUNCTION IN ADULT PROTEIN-CALORIE MALNUTRITION. *(E.)* Kumar, R.; Banks, P. A.; George, P. K.; Tandon, B. N. (All India Inst. Med. Sci., New Delhi). *Gastroenterology* 68(6):1593-1595, 1975.

The early pattern of recovery of pancreatic exocrine function in response to a high protein diet was studied in 9 patients (6 men and 3 women, aged 20-70 yr) whose dietary histories indicated prolonged intake of food low in calories and deficient in protein. All patients showed symptoms of diarrhea, weakness, and peripheral edema. Pancreozymin-secretin tests were performed. The patients were placed on a diet which provided 50 cal/kg composed of 20% calories from animal protein of high biological value, 55% calories from fat, and 25% calories from carbohydrate. Repeat studies of pancreatic exocrine function were performed at 2 weeks and at 6 weeks after dietary therapy was instituted. The volume of basal and stimulated pancreatic flow was not significantly altered by the high-protein diet. There was significant improvement in the maximal bicarbonate concentration at 2 weeks but no additional improvement at 6 weeks. The maximal bicarbonate concentration of 71.3 mEq/liter at 2 weeks and 76.0 mEq/liter at 6 weeks are still subnormal compared with control volunteers in India. A significant improvement in protease secretion after 2 weeks was sustained but not increased after 6 weeks on the high-protein diet. The results of this study confirm the characteristic secretory deficit in adult protein caloric malnutrition and reveal that there is substantial improvement in pancreatic exocrine function after only 2 weeks of dietary therapy with improvement in maximum bicarbonate concentration and increased protease secretion. This rapid improvement indicates that there is considerable regenerative ability in the pancreas of man despite long-standing severe protein calorie malnutrition.

6482 DIFFERENTIAL MEASUREMENT OF SMALL AND LARGE BOWEL TRANSIT TIMES IN CONSTIPATION AND DIARRHOEA: A NEW APPROACH. *(E.)* Waller, S. L. (Cent. Middlesex Hosp., London, England). *Gut* 16(5):372-378, 1975.

A method which allows the transit time through the small and large intestine to be differentiated was studied in 13 patients. Seven of the patients had diarrhea, which was caused by the irritable bowel syndrome (three), vagotomy and pyloroplasty (three), and laxative abuse (one). Just before breakfast each patient received a radiotelemetering capsule containing a disc of filter paper impregnated with 5 to 10 μCi of ^{51}Cr. After breakfast each was given 25 radioopaque pellets. The position of the capsule was plotted at intervals from zero to 10 and 12 hr daily. Plots were made every 15 to 20 min for the stomach and small intestine and every 30 to 60 min for the colon. Gastric emptying and small intestinal transit were similar in all patients. In contrast, colonic transit was faster in patients with diarrhea (17.5 hr) than in controls (118 hr). Senna was administered to four constipated subjects and produced a transit plot and elimination of the pellets and capsule which resembled diarrheal states in two of the four. In the other two patients, senna caused neither movement of the capsule nor bowel action. One diarrheal subject was restudied while taking codeine phosphate (60 mg over a 6-hr period). Small intestinal transit time was prolonged by only 2 hr, but the capsule remained in the colon an extra 34 hr. It is concluded that this new method allows differential measurement of small and large bowel transit times in man, thus allowing frequent observations of movements of colonic contents to be made without recourse to radiographs. The method is time consuming, but technically simple, avoids intubation, and gives much information with minimal irradiation of the patient. It is concluded that fast colonic transit is a striking feature of diarrhea.

6483 RELATIVE ABUNDANCE OF BIG AND LITTLE GASTRINS IN THE TUMOURS AND BLOOD OF PATIENTS WITH THE ZOLLINGER-ELLISON SYNDROME. *(E.)* Dockray, G. J.; Walsh, J. H.; Passaro, E., Jr. (VA Wadsworth Hosp. Cent., Los Angeles, Calif.). *Gut* 16(5):353-358, 1975.

The relative concentrations of big gastrin (G-34) and little gastrin (G-17) were compared in the sera and tumors (gastrinomas) of five Zollinger-Ellison syndrome patients. Big and little gastrins were identified in all ten serum samples and in all ten tumor biopsies examined. In serum, G-34 (range of concentrations, 58 to 220,000 fM/ml) was the major form of gastrin and G-17 (22 to 78,000 fM/ml) was a minor component. The mean relative abundance of G-17 (G17/[G17 + G34]) in serum was 0.18 and the mean relative abundance of G-34 was 0.82. In tumor, however, the opposite was true. G-17 (49 to 869,000 pM/g) was the major component and G-34 (45-464 pM/g) a minor component, and the relative proportions of G-17 and G-34 were 0.73 and 0.27, resp. Following an i.v. injection of porcine secretin (2.0 U/kg), there was a rapid increase in concentration of all forms of gastrin in the blood, but the increase in G-17 was proportionately greater than that of G-34 (relative abundance of G-17 in basal serum was 0.21 compared with 0.37, 5 min after secretin administration). Differences in the half lives of G-17 and G-34 may partly explain their relative abundancy in serum and tumor tissues. It is noted that G-17 is about seven times more potent than G-34 in stimulating acid secretion when potencies are expressed in terms of serum concentration. Thus, although G-17 constituted only about 20% of the serum gastrin immunoreactivity, its contribution to the biological activity in serum was the most important circulating form of gastrin.

6484 KAPOSI'S SARCOMA OF THE STOMACH AND DUODENUM: ENDOSCOPIC AND ROENTGENOLOGIC CORRELATIONS. *(E.)* Ahmed, N.; Nelson, R. S.; Goldstein, H. M.; Sinkovics, J. G. (M. D. Anderson Hosp. Tumor Inst., Houston, Tex.). *Gastrointest. Endosc.* 21(4):149-152, 1975.

To stress the occurrence, clinical presentation and management of gastrointestinal involvement with Kaposi's sarcoma, with particular emphasis on the endoscopic and radiological means of diagnosis and evaluation during treatment, four case reports are presented. Biopsies confirmed the diagnosis of Kaposi's sarcoma in the first case, a 68-yr-old man. Physical examination revealed widespread typical cutaneous lesions, hepatomegaly, diminished peripheral pulses in the lower extremity, and a right pleural effusion yielding Karposi's sarcoma cells on cytological examination. Gastroduodenoscopy showed numerous, purple macular lesions in the body of the stomach, in addition to sessile polypoid lesions (0.5-1.5 cm in diameter). Chemotherapy produced total regression of lesions with only two tiny white polypoid areas in the body of the stomach; the skin lesions remained unchanged after an initial, partial regression. The second case (a 60-yr-old man) showed cutaneous lesions and splenomegaly. Gastroscopy showed several 1 to 2 cm lesions at the junction of the body and the fundus of the stomach, in addition to similar 4 to 5 mm lesions present more distally along the greater curvature. Chemotherapy produced complete regression of the gastric lesions, but produced no response in skin involvement. A double-contrast view of the stomach in the third case (a 77-yr-old man) showed bulbous enlargement of two gastric rugae and a small nodular filling defect along the lesser curvature. An upper gastrointestinal radiograph demonstrated a target lesion of the upper body of the stomach in the fourth case (a 65-yr-old man), composed of a submucosal filling defect with a central collection of barium. Both these patients were treated with chemotherapy, and the outcome awaits further evaluation. The majority of upper gastrointestinal lesions in Kaposi's sarcoma were found in the stomach at endoscopy. There are three distinct types: maculopapular; nodular and polypous; and nodular with central umbilication. It is concluded that the visceral involvement in Kaposi's sarcoma is probably a manifestation of multicentricity rather than metastasis.

6485 EFFECT OF MICROORGANISMS ISOLATED FROM THE UPPER GUT OF MALNOURISHED CHILDREN ON INTESTINAL SUGAR ABSORPTION IN VIVO. *(E.)* Gracey, M.; Burke, V.; Thomas, J. A.; Stone, D. E. (Princess Margaret Children's Medical Res. Foundation, Perth, Western Australia). *Am. J. Clin. Nutr.* 28(8):841-845, 1975.

The effect of excessive numbers of microorganisms, cultured from the duodenum of malnourished children, on the intestinal transport of sugar was investigated. Adult Wistar rats (150-300 g) were used and a 20 cm segment of the jejunum was selected as a test site for the absorption of arbutin (p-hydroxyphenyl-β-glucoside). Several varieties of microorganisms were capable of interfering with absorption of sugar: lactobacillis, all species of *E. coli, Klebsiella, Pseudomonas, C. albicans* and *C. parapsilosis*. Cultures of *Staphylococcus saprophyticus, Salmonella paratyphi, Shigella, Proteus* and *C. tropicalis* did not have an inhibitory effect. Whether the observed effects were due to direct action of the organisms or to a toxin or other metabolic by-product requires further study. The fact that some of the organisms connected with inhibition were not considered enteropathogenic suggests that concepts of enteropathogenicity may require revision.

6486 ENTEROTOXIGENIC Escherichia coli-ASSOCAITED DIARRHEAL DISEASE IN APACHE CHILDREN. *(E.)* Sack, R. B.; Hirschhorn, N.; Brownlee, I.; Cash, R. A.; Woodward, W. E.; Sack, D. A. (Univ. Oregon Med. Sch., Portland). *N. Engl. J. Med.* 292(20):1041-1045, 1975.

A search for intestinal enterotoxigenic *Escherichia coli* was made in 59 Apache children hospitalized with 64 episodes of acute diarrhea. *E. coli* isolated from acute-phase and convalescent-phase specimens of small bowel fluid and stool were tested in three recognized models: the adult rabbit ileal loop, infant rabbit, and the adrenal-cell assay. Enterotoxigenic strains were isolated from ten children during acute diarrheal episodes (16%). None were isolated from convalescent-phase specimens. None of 64 enteropathogenic serotypes of *E. coli* from 43 children with diarrhea, however, caused fluid production in the ileal-loop model. These results suggest that enterotoxigenic *E. coli* may be the cause of considerable diarrhea in this population and that the term "enteropathogenic" as applied to serotypes of *E. coli* needs to be redefined.

GENERAL

Parasitology

6544 TRYPTIC ACTIVITY IN THE DUODENAL ASPIRATE FOLLOWING A STANDARD TEST MEAL IN GIARDIASIS. *(E.)* Chawla, L. S.; Sehgal, A. K.; Broor, S. L.; Verma, R. S.; Chhuttani, P. N. (Postgraduate Inst. Medical Education Res., Chandigarh, India). *Scand. J. Gastroenterol.* 10(4):445-447, 1975.

Tryptic activity was studied in the duodenal aspirate of giardiasis patients after a standard test meal. The diagnosis of giardiasis was made in 26 patients (17 men and nine women, aged 14-60 yr) by repeated stool examinations. Duodenal juice was collected for two hr after a meal containing 45 g glucose, 18 g soya bean oil, and 15 g dried milk protein powder in 300 ml warm water. Tryptic activity was estimated using synthetic α-N-benzoyl-L-arginine ethyl ester as a substrate. The patients were treated with furazolidine (100 mg/day for 7 days). The mean tryptic activity for 20 normal controls ranged from 12.7-27.5 μEq/min/ml, with the lower limit of normal at 8.9 μEq/min/ml. The mean tryptic activity in the giardiasis group before treatment ranged from 3.4-26.7 μEq/min/ml. There was a highly significant difference between this group and controls. Values below 8.9 μEq/min/ml were found in 10 cases (38.46%), all with diarrhea. A marked rise in tryptic activity was seen in nine patients restudied at least two weeks after completion of therapy, ranging from 10.9-26 μEq/min/ml. The difference in pre- and post-treatment values was highly significant. These data demonstrate a low tryptic activity in giardiasis; however, the mechanisms governing this activity are not clear.

6545 MEBENDAZOLE (R 17635) IN ENTEROBIASIS: A CLINICAL TRIAL IN MENTAL RETARDATES. *(E.)* Lormans, J. A. G.; Wesel, A. J. T.; Vanparus, O. F. (Inst. Ment. Retardates 't Honk, Veldhoven, The Netherlands). *Chemotherapy* 21(3/4):255-260, 1975.

The efficacy of mebendazole against enterobiasis was tested on 150 institutionalized mental retardates (age range, 5-25 yr). At the start of the trial all patients swallowed a tablet containing 100 mg of mebendazole. Another tablet was administered to all patients 2 weeks and 1, 2, and 3 months later. Further treatment with one tablet was given to 19 patients, 4 and 5 months after the start of the trial. The presence of *E. vermicularis* was checked with cellophane adhesive tapes from the anal skin and from the right-hand fingertips before the trial and after 1, 3 and 6 months. Of 150 subjects, 94 were positive before the trial. At the first post-treatment examination, all patients were negative. However, 12% were eventually reinfected. No side effects were observed or reported. These data confirm the efficacy of mebendazole in the treatment of oxyuriasis, and its lack of adverse effects.

6546 WHIPWORM DYSENTERY. *(E.)* McCaffery, T. D.; (Louisiana State Univ. Sch. Med., New Orleans). *Gastrointest. Endosc.* 21(4):172-173, 1975.

A rare case of non-inflammatory bowel disease due to whipworm infection was presented. A black female of 16 yr presented with vomiting and diarrhea of six weeks duration. Physical examination revealed evidence of dehydration. The abdomen was flat, nontender, and negative for palpable masses. Stools were positive for occult blood, and revealed *Trichuris trichiura* ova (450/direct smear) and *Entameba histolytica* trophozoites. Proctoscopy revealed massive numbers of worms attached to a friable mucosa. Colonoscopy to 40 cm revealed minimum disruption of the mucosa proximal to the friable portion, but massive numbers of worms were seen throughout. Hexylresorcinol (0.2%) retention enemas and tetracycline (one g daily for 10 days) gradually reduced egg count to 79/direct smear. *E. histolytica* infection was no longer evident on multiple follow-ups, and the dysentery cleared. No conclusions are drawn.

6547 ALTERATIONS IN NORMAL ESOPHAGEAL MOTILITY IN PATIENTS WITH CHAGAS' DISEASE. *(E.)* Csendes, A.; Strauszer, T.; Uribe, P. (Hosp. J. J. Aguirre, Santiago, Chile). *Am. J. Dig. Dis.* 20(5):437-442, 1975.

Patients with Chagas' disease but with no esophageal involvement were followed-up to determine whether there was progression toward achalasia. Diagnosis of chronic Chagas' disease in the eight patients was based on visceral compromise (megacolon and heart A-V block), positive hemagglutination, and positive complement binding serologic tests. For radiologic examination, 4-6 spot films were taken of the esophagus and esophogastric junction in each case. The maximal internal diameter of the middle third of the esophagus and the esophogastric junction were reviewed independently by two of the authors and expressed in mm. For manometric studies, an assembly of two or three catheters was introduced through the nose or mouth up to the fundus of the stomach, and the sensors were withdrawn in one cm increments. In five patients without heart disease, 2.5 mg betamethylcoline was injected s.c. and a second pull-through was performed after 20-30 min. Relaxation was recorded as 100% when sphincter and fundic pressures were equal, and as 0% when no relaxation occurred. Follow-up after the first study ranged from 24-87 months later. The radiological studies showed no significant change other than an increase in internal esophageal diameter. Resting gastroesophageal sphincter pressure did not change significantly after a mean follow-up of 64 months. Mean sphincter length was 3.20 cm in the first study and 3.05 in the second. There was complete sphincter relaxation in five patients and partial relaxation in one in the first study. In the second study, two additional patients showed partial relaxation. Mean resting intraesophageal pressure was -3.2 mm Hg in the first study and -3.5 mm Hg in the second. Mean peristaltic wave amplitude showed an increase during the second study, but wave duration did not vary. In the first study, 76% of the waves were peristaltic compared to 89% in the second. After injection of betamethylcoline, three patients showed a significant rise in gastroesophageal sphincter pressure; two showed no increase. It is concluded that there is no direct link between the esophageal motility of achalasia and that of Chagas' disease with respect to gastroesophagealsphincter pressure response and betamethylcoline-induced spontaneous activity.

6548 INTESTINAL MALABSORPTION IN ACUTE INFECTION WITH Strongyloides stercoralis.

(E.) O'Brien, W.; (R. Army Med. Coll., London, England). *Trans. R. Soc. Trop. Med. Hyg.* 69(1):69-77, 1975.

An acute malabsorption syndrome, apparently resulting from early *Strongyloides stercoralis* infection, was described. The patients were seven infantry soldiers stationed in Borneo. Of them, six presented with acute diarrhea with liquid stools. The seventh presented with massive eosinophilia and associated respiratory symptoms, but developed diarrhea within four days of admission to the hospital. After admission, all were passing 4-6 loose, foul stools with a frothy appearance daily. One had abdominal colic, three had had a transient rash 2 weeks before the diarrhea, and two had had episodes of coughing, breathlessness and wheezing about the same time. Intestinal function tests showed severe steatorrhea (25-42 g/day) to be present in three cases, and moderate to mild (7.0-13 g/day) in four cases. The D-xylose test was normal, but absorption of vitamin B_{12} with intrinsic factor was subnormal in four (8.5-25%). Barium meal examination showed thickened traverse mucosal folds in two. Jejunal biopsy specimens showed a pattern of "fingers" and/or "leaves" in six, and "leaves" and ridges in one. Microscopically, the ridges showed partial villous atrophy. The villi were swollen and the vascular pattern was indistinct. Intestinal mucosa was edematous in four. In two there was heavy eosinophil infiltration. Two patients were mildly anemic. The patient with partial villous atrophy had a hemoglobin concentration of 11.8/100 ml, the marrow was megaloblastic, and serum folate was 1.6 ng/ml (it was 2-5.9 ng/ml in the other six). All showed considerable eosinophilia (over 20,000/mm^3 in two, and over 6000/mm^3 in another three). Rhabditiform larvae of *S. stercoralis* were found in the stools of one patient and in the duodenal aspirate of a second. Hookworm ova were found in these two and in three other patients. Three were treated with bephenium hydroxynaphthoate with no effect, and one received tetrachlorethylene without effect. All responded well to dithiazanine treatment. In one patient B_{12} malabsorption persisted, but returned to normal after a week of aureomycin therapy. It is concluded that the malabsorption may have been due to a hypersensitive reaction to the worms, with histamine release from intestinal mucosa mast cells.

6549 PRECIPITATING ANTIBODIES AGAINST Entamoeba histolytica IN LIVER PUS: A PRELIMINARY COMMUNICATION.

(E.) Mahajan, R. C.; Ganguly, N. K.; Chitkara, N. L.; Dutta, D. V.; Chhuyyani, P. N. (Postgrad. Inst. Med. Educ. Res., Chandigarh, India). *Indian J. Med. Res.* 63(2):229-231, 1975.

The presence of precipitating antibodies against amebic antigen in liver pus was investigated and its titers were compared with those in serum. Pus samples were obtained from 15 cases of amebic liver abscess. Amebic immunofluorescence and indirect hemagglutination tests were positive in all cases. In each case, 20 ml of aspirate was centrifuged. The resulting supernatant and a serum sample from each patient were tested by counterimmunoelectrophoresis. Of the patients, 11 (73.3%) tested positive for amebiasis (using pus) and 14 (93.3%) tested positive using serum. Antibody titers in the serum specimens (10 were from 1:4 to 1.8) were always higher than those in the pus (nine, neat only; three 1:4). It is concluded that liver pus aspirate can be a diagnostic adjunct in hepatic amebiasis cases.

6550 DETECTION BY IMMUNOFLUORESCENCE OF ANTIBODIES TO PARASITIC AGENTS. USE OF CLASS-SPECIFIC CONJUGATES.

(E.) Huldt, G.; Ljungstrom, I.; Aust-Kettis, A. (Natl. Bacteriol. Lab., Stockholm, Sweden). *Ann. N.Y. Acad. Sci.* 254:304-314, 1975.

Class-specific conjugates were used to study the immunoglobin (Ig) response to parasitic agents in human sera. Sera from patients with toxoplasmosis, trichinosis, South European echinococcosis, and schistosomiasis were examined by immunofluorescence (IF) using class-specific conjugates. The conjugates were also examined for Ig class specificity with *Toxoplasma* antigen, and were tested by IF for direct reactivity with each parasite. Sixteen of the 18 conjugates tested showed Ig class specificity and none reacted directly with any of the parasitic antigens. For each parasite-antibody system, chessboard titrations yielded optimum working dilutions for each conjugate; these titrations gave somewhat different results with the same conjugate in different parasite systems. In 5 infants, congenital toxoplasmosis was diagnosed by the presence of IgM antibodies in the cord blood or serum taken a few days after birth; in these cases IgM was demonstrated over periods of 2-4 months. Conversely, specific IgM antibodies were not detectable in sera taken from 3- to 12-month-old children with the congenital disease. Long-term follow-up studies of patients with acquired toxoplasmosis and trichonosis revealed demonstrable IgM and/or IgA antibodies in the early stage of infection (0-1 month). In toxoplasmosis, the IgA antibodies disappeared before the IgM antibodies, and in both infections, the eventual decrease in specific IgM antibody was associated with a rise in specific IgG antibody titer. Among 103 sera from patients with schistosomiasis, all were positive for IgG antibodies, 34% had IgM antibodies, and 6% had IgA antibodies; many of these patients had little or no clinical symptoms. In serum samples from Scandinavian Lapps with echinococcosis but no demonstrable circulating antibodies, antigenic stimulation was followed by a secondary antibody response to antibodies of the IgM and/or IgA classes. The results indicate that the use of IF for the detection of class-specific immunoglobulin response to parasitic agents can provide a reasonably specific and reproducible test if performed under optimal conditions;

the demonstration of specific IgM and/or IgA antibodies by this test probably indicates recent antigenic stimulation.

6551 COMPARISON OF METRONIDAZOLE AND CHLOROQUINE FOR THE TREATMENT OF AMOEBIC LIVER ABSCESS. A CONTROLLED TRIAL. *(E.)* Cohen, H. G.; Reynolds, T. B. (Univ. South. California Sch. Med., Los Angeles). *Gastroenterology* 69(1):35-41, 1975.

Chloroquine and metronidazole were compared in a randomized trial for the treatment of amebic liver abscess in 36 patients. An additional 30 patients were treated without randomization. The total patient population of 66 individuals was composed of 50 males and 16 females, aged 4 to 74 yr. Chloroquine was administered at a dose level of 500 mg daily for 10 weeks. Metronidazole was given in a dose of 750 mg, 3 times/day for 10 days. Criteria for the diagnosis of amebic abscess included: a suitable clinical picture, filling defect on hepatic scan, high titer of antibody of *Entamoeba histolytica* by indirect hemagglutination, and eventual complete recovery with treatment or appropriate findings on autopsy examination. Treatment failure was defined as illness that persisted beyond 10 days or recurred after that time. Such failure occurred in one out of 28 patients treated with chloroquine and in two out of 36 treated with metronidazole. In two patients who died it was difficult to assess the results of drug therapy. All three failures had unusually large filling defects on scan, and all three showed some improvement with treatment so that pyogenic abscess seemed unlikely. It is concluded that both drugs are highly effective in the treatment of amebic liver abscess.

GENERAL

Regional Enteritis

6577 CROHN'S DISEASE OF THE APPENDIX. PRESENTATION OF A CASE WITH REVIEW OF THE LITERATURE. *(E.)* Weiss, Y.; Durst, A. L. (Cent. Emek Hosp., Afula, Israel). *Am. J. Gastroenterol.* 63(4):333-339, 1975.

An obese 26-yr-old male was admitted as an emergency case with a 6-day history of lower abdominal pain, which irradiated into both flanks and was initially mild. On the fifth day, the pain suddenly increased and his temperature rose to 39.9 C. On admission the patient showed marked direct and rebound tenderness in the right lower quadrant with muscle guarding. An ill-defined mass was palpated in the right iliac fossa. Diagnosis of acute appendicitis was made. At operation a large retrocecal mass was found very close to the right common iliac artery. The mass contained the gangrenous appendix and pus. The appendix was removed without burying the stump and a Penrose drain was left in the abscess cavity. The terminal ileum showed no pathological changes. On the basis of this case and many cited from the literature it is concluded that a surgeon should not hesitate to remove the appendix in the presence of regional enteritis for two reasons. First, the appendix may become the site of Crohn's disease, and second, patients with Crohn's disease may occasionally develop acute appendicitis. Indeed, all cases of Crohn's disease of the appendix showed acute appendicitis superimposed on the granulomatous lesion. Since in a patient with known Crohn's disease, the clinical picture may be interpreted as an acute exacerbation of the basic disease, one may be tempted to procrastinate, thus exposing the patient to possible complications.

6578 METRONIDAZOLE FOR CROHN'S DISEASE. *(E.)* Ursing, B.; Kamme, C. (Univ. Hosp., Lund, Sweden). *Lancet* 1(7910):775-777, 1975.

The use of metronidazole in the treatment of Crohn's disease was investigated in 5 patients (2 men and 3 women, aged 8-26 yr) who differed in respect to duration of disease (4 months to 10 yr), symptoms (diarrhea, abdominal pain, fever, anorexia, weight loss, and sideropenic anemia), and intestinal involvement. The response to metronidazole was the same in 4 of the 5 patients. The patients received a high dose of metronidazole (up to 40 mg/kg/day) which was later reduced to about 30 mg/kg/day. Even though they received the same doses, serum metronidazole levels varied considerably from one patient to another, ranging from 5-35 µg/ml at 2-3 hr after administration of metronidazole to 2-20 µg/ml at 8 hr after drug administration. The drug-related symptoms of nausea, vertigo, and tiredness developed in all patients. Two patients developed paresthesia and hyperesthesia. Neurological examinations showed no abnormalities. Liver function tests and blood picture were normal. All side effects ceased after reduction of the dose. In response to the drug, abdominal pain diminished and defecation became less frequent. The patients gained weight and tolerated a normal diet. In one case, withdrawal of the drug caused a return of symptoms which again disappeared on reinstitution of metronidazole. In one patient, the response to metronidazole was obscure: no improvement was noted until 4 months of metronidazole treatment, and corticosteroids were reintroduced. This patient had higher serum metronidazole levels than those who showed a rapid improvement on the same dose. The response to this drug suggests that anaerobes are involved in the pathogenesis of Crohn's disease. The return to normal of the serum proteins suggested that treatment suppressed the inflammatory processes of the intestines. Of an additional 12 patients, most of them on about 20 mg/kg/day, 9 have shown a rapid clinical improvement, indicating that lower doses than those used in this study may be successful.

6579 CLINICAL MANIFESTATIONS OF CROHN'S DISEASE IN CHILDREN AND ADOLESCENTS. *(E.)* Burbige, E. J.; Huang, S. S.; Bayless, T. M. (Johns Hopkins Univ. Sch. Med., Baltimore, Md.). *Pediatrics* 55(6):866-871, 1975.

The clinical features of 58 patients (37 boys and 21 girls younger than 15 yr of age) with Crohn's disease of the small intestine and/or of the colon are summarized with emphasis on the prominence of extraintestinal manifestations. Nine patients had familial incidence of Crohn's disease or ulcerative colitis. The sites of involvement for these patients included: ileum, 18; ileum-right colon, 12; jejunum-ileum, nine; colon only, eight; duodenum-jejunum-ileum, five; jejunun-ileum-right colon, one; ileum-left colon, one; duodenum, one; and acute ileitis, three. Clinical manifestations included: abdominal pain, 86%; fever, 83%; diarrhea, 72%; growth retardation, 30%; joints, 25%; anorectal disease, 24%; bleeding, 14%; and rash, erythema nodosum, 10%. The average delay in obtaining the correct diagnosis was 13.7 months and ranged from 1 month to 7 yr. The site of the bowel involved was related to the length of the delay. Laboratory results included: increased ESR, 84%; increased WBC, 70%; decreased serum albumin, 64%; hypochromic anemia, 50%; and gastrointestinal blood loss, 36%. The results suggest that the symptoms and signs of Crohn's disease in children are often subtle and generally nonspecific. Crohn's disease should be considered a differential diagnosis of children with prolonged fever or arthralgia even without obvious gastrointestinal complaints. Of the 58 children in this study, 22 were originally thought to have diseases outside the gastrointestinal tract. Proctosigmoidoscopy, barium enema, and small-bowel series are the most useful diagnostic procedures. It is felt that an awareness of the manifestations of Crohn's disease in children as well as a high index of suspicion should shorten the delay before this diagnosis is established.

6580 LEUKOCYTE MIGRATION TEST IN CROHN'S DISEASE, ULCERATIVE COLITIS, AND ANKYLOSING SPONDYLITIS USING CROHN'S COLON HOMOGENATE, MITOCHONDRIAL, AND MICROSOMAL FRACTIONS. *(E.)* Williams, M. J.; Richens, E. R.; Gough, K. R.; Ancill, R. J. (R. United Hosp., Bath, England). *Am. J. Dig. Dis.* 20(5):425-429, 1975.

Leukocytes from 33 patients with Crohn's disease (20 females and 13 males, aged 16-66 yr), 20 patients with ulcerative colitis (15 females and 5 males, aged 16-71 yr) and 20 patients with ankylosing spondylitis (six females and 14 males, aged 16-53 yr) were tested for evidence of abnormal migration in the presence of preparations of colon from a patient with Crohn's disease. In the 33 patients with Crohn's disease, the disease was confined to the large bowel in nine, the small bowel in eight, and involved both large and small intestines in 16. None of the patients studied was undergoing treatment with immunosuppressive drugs. The same test was later performed with leukocytes from 12 healthy controls. Antigen preparations used were colon mucosal homogenate, and colon mucosal mitochondrial and microsomal fractions. The results of this study indicate that a high proportion of Crohn's disease patients have circulating lymphocytes sensitized to constituents of the diseased colonic mucosa. There are also similarities of cellular immunity between Crohn's disease and ulcerative colitis. Lymphocytes from patients with both diseases showed equal cytotoxicity to autologous and allogeneic colon cells. This phenomenon is most marked when the antigens used are the mitochondrial and microsomal fractions of the colonic mucosa. In the ulcerative colitis group, however, there was no evidence of cellular hypersensitivity to these subcellular fractions, and only minimal hypersensitivity to colonic mucosal homogenate. Therefore, this test seems to differentiate between the two diseases. Of the patients with ankylosing spondylitis, one also had Crohn's disease. With each of the three antigens used, a high percentage of patients showed stimulation of leukocyte migration. It is suggested that this may reflect weak sensitization to the antigens as opposed to the strong sensitization manifested by inhibition obtained in the Crohn's disease group. These facts may represent the opposite ends of a hypersensitivity spectrum to an antigen of common significance in the etiology or perpetuation of the disease.

6581 SOME SERUM PROTEIN STUDIES IN CROHN'S DISEASE AND ULCERATIVE COLITIS. *(E.)* Sandor, G.; Levy, E.; Malafosse, M.; Huguet, C.; Huguier, M.; Loygue, J. (Pasteur Inst., Paris, France). *Res. Commun. Chem. Pathol. Pharmacol.* 11(1):129-145, 1975.

In studying the pathogenetic factors involved in the clinical picture for Crohn's disease and ulcerative colitis, 81 determinations were carried out on about 60 cases of Crohn's disease and 73 determinations on about 50 cases of ulcerative colitis. Nine individual serum proteins were evaluated by the immunochemical radial diffusion technique: albumin, transferrin, orosomucoid, ceruloplasmin, beta-1-C-globulin, alpha-2-M-globulin, IgG, IgM and IgA. An increase in IgA, isolated or associated with that of IgM, indicated Crohn's disease; an isolated increase in IgM indicated ulcerative colitis. A significantly increased ceruloplasmin level indicated Crohn's disease; no significant immunoglobulin increase indicated ulcerative colitis. When at least two of the three major immunoglobulins increased, Crohn's disease was indicated; significantly diminished alpha-2-M-globulin indicated ulcerative colitis. An absolute albumin value of less than 20% of normal indicated Crohn's disease. When orosomucoid was highly elevated and albumin was strikingly decreased, both enterites were in acutely evolutive states. The data do not favor the hypothesis of an autoimmune origin, especially for ulcerative colitis. A prevailing IgA synthesis took place in Crohn's disease in which a mostly healthy epithelium is kept intact, but IgM synthesis prevails in ulcerative colitis, in which the mucosal epithelium is broadly destroyed. The data support the theory of a virus as the causative agent for Crohn's disease and ulcerative colitis.

6582 ORAL MANIFESTATIONS OF CROHN'S DISEASE. *(E.)* Basu, M. K.; Asquith, P.; Thompson, R. A.; Cooke, W. T. (Dep. Oral Pathol., Birmingham Univ., England). *Gut* 16(4):249-254, 1975.

The incidence of oral lesions in 100 patients with Crohn's disease (38 men and 62 women) was compared to the incidence in 100 controls and in 100 patients with ulcerative colitis (42 men and 58 women). Of these 300 individuals, nine persons with Crohn's disease (six females and three males, aged 21 to 72 yr), two with ulcerative colitis, and one normal control had oral lesions. Of the Crohn's disease patients with oral lesions, eight had involvement of both the small and large intestine. Perianal disease was found in six, and one had an eczematous skin lesion. The oral lesions macroscopically and histologically resembled those seen in the gastrointestinal tract in Crohn's disease, suggesting they were due to the same disease process. However, typical sarcoid-like granulomas were not seen. Lesions in ulcerative colitis were different macroscopically and histologically. There were no significant differences in the mean values or the incidence of low levels for serum folate, B_{12}, or serum iron between Crohn's disease patients with or without oral lesions. In contrast, an increased number of patients with oral lesions had raised serum seromucoid levels and low serum albumin levels. The parotid secretion rates of IgA for healthy controls and Crohn's patients did not differ significantly. However, Crohn's patients with raised serum seromucoid and low serum albumin had significantly lower IgA secretion rates. It is suggested that in patients with active Crohn's disease, IgA plasma cells destined for the parotid gland are diverted to the site of maximum antigenic stimulation in the bowel. Then the relative lack of IgA in the mouth of such patients allows invasion of the oral mucous membrane by food or bacterial antigens in the mouth, so producing an oral lesion.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Office
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-03
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1975.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *World Medical Periodicals*, 3rd Edition, are used.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

6594 ENDOCRINE CELLS OF THE INTESTINAL MUCOSA. II. NON-ARGENTAFFIN CELLS. *(Pol.)* Lamprecht, J. (Inst. Cell Pathophysiol., CMKP, Warsaw, Poland). *Patol. Pol.* 25(4):595-602, 1974.

Identification and characterization of endocrine cells (EC) of the intestinal mucosa, as well as their functional correlation with intestinal hormones presumably generated by them, was studied directly by electron microscopy and indirectly from other sources. The group of cells in question, morphologically and functionally different from other types of endocrine cells of the intestinal mucosa (especially those of EC cells), designated as nonargentaffin cells, include at least seven individual types of endocrine cells identified by electron microscopy (by the author), or by some other methods (by other researchers): type S (found mostly in duodenum); type EG (in rectum); type I (in duodenum); D (in stomach); D_1 (in duodenum); A-like (in stomach); and T (in duodenum). So far, only two different hormones could be associated with certainty with individual types of nonargentaffin cells as their sources of generation: secretin--with cell type S; and enteroglucagon--with cell type EG. To pursue further the investigation of correlation between specific nonargentaffin cells and individual intestinal hormones, the author recommends the intensification of immunological studies at the electron-microscopic level.

6595 AN UNUSUAL MODIFICATION OF ENDOPLASMIC RETICULUM IN EPITHELIAL CELLS OF THE MOUSE ASCENDING COLON. *(E.)* Michaels, J. E. (Dep. Anatomy, McGill Univ., Montreal, Quebec, Canada). *Anat. Rec.* 183(1):27-38, 1975.

A rarely occurring modification of the endoplasmic reticulum in the epithelium of the ascending colon of the mouse was studied in outbred adult male CD-1 animals. The mice were perfused through the descending thoracic aorta with fixative, after which the colonic tissue was sectioned and observed under a Siemens Elmiskop 1A microscope. The modified endoplasmic reticulum consisted of a stack of 3 to 15 parallel cisterna-like elements separated by regular intervals of about 67 nm. The stacked cisternae were usually located adjacent to the basal end of the nucleus or in the region between the nucleus and the basal cell membrane. The top and bottom cisternae of many of of the stacks had patent lumens and their outer membranes were lined by ribosomes. Although the middle cisternae most frequently had attenuated lumens in their central regions, in some instances the width of the cisternal lumens was similar throughout. Closely apposed pairs of cisternae were also observed, and some of the stacks had a concentric configuration. The intercisternal space contained tightly packed vesicles about 38 nm in diameter which were arranged in a hexagonal pattern. Many of the vesicles were connected to the membranes of the cisternae by stalk-like projections, but the vesicles also occurred between the nuclear envelope and the adjacent parallel cisternae. Mitochondria were situated close to each stack. The vesiculated stacked cisternae appeared to be distinct from the annulate lamellae in several respects, although it is likely that some of the previously reported neuronal lamellar structures are closely related or identical to the vesiculated stacked cisternae. It is highly unlikely that these cisternae are mere artifacts despite their infrequent occurrence.

6596 IMMUNOCHEMICAL STUDIES OF THE ENDOCRINE CELLS OF THE GASTROINTESTINAL TRACT. I. THE USE AND VALUE OF PEROXIDASE-CONJUGATED ANTIBODY TECHNIQUES FOR THE LOCALIZATION OF GASTRIN-CONTAINING CELLS IN THE HUMAN PYLORIC ANTRUM. *(E.)* Robinson, G.; Dawson, I. (Dept. Pathology, Univ. Nottingham, England). *Histochem. J.* 7(4):321-333, 1975.

Light microscopic and immunochemical localization of gastrin-containing cells in cryostat sections of human pyloric antrum were reported. Parallel electron microscope studies were also carried out. Specimens of grossly normal antral mucosa were obtained from patients after pyloroplasty for duodenal ulcer or gastrectomy. All samples were either fresh-frozen or pre-fixed in 4% formaldehyde. The immunological reagents included: rabbit anti-human gastrin serum, glutaraldehyde-activated horseradish peroxidase and peroxidase-conjugated swine anti-rabbit IgG. Cryostat sections were single- or double-stained using direct or indirect techniques. No gastrin-containing cells were localized in fresh-frozen, postfixed tissue, or in unfixed fresh-frozen sections. Staining of sections from paraformaldehyde-fixed blocks by direct and indirect single stain methods using 3,3'-diaminobenzidine tetrahydrochloride (DAB) as a substrate showed the presence of gastrin-containing cells in the antral mucosal glands. Many cells containing either endogenous peroxidase or heme derivatives were also intensely stained by DAB. Preincubation of sections in 0.1 M sodium azide, potassium cyanide, sodium nitroferrocyanide or 3-amino-1,2,4-triazole inhibited endogenous peroxidase activity in the cytoplasmic components of antral mucosal cells, but the macrophages, neutrophils, eosinophils and erythrocytes still stained after DAB treatment. Gastrin-containing cells in prefixed cryostat sections were also demonstrated by both the direct and indirect double-staining techniques. These cells stained a different color from those containing endogeneous peroxidase or substances giving a pseudoperoxidase reaction. No gastrin-containing cells were stained in control sections. The distribution and variation in shape exhibited by the gastrin-containing cells localized by these immunoperoxidase methods were similar to those previously found using immunofluorescent techniques. The methods used in this study, providing a permanent preparation which can be examined under normal bright field illumination, are suggested as useful alternatives to fluorescent methods.

6597 CELL POPULATION KINETICS IN THE MOUSE JEJUNAL CRYPT. *(Eng.)* Al-Dewachi, H. S.; Wright, N. A.; Appleton, D. R.; Watson, A. J. (Dept. Pathology and Medical Statistics, Univ. Newcastle upon Tyne, Newcastle upon Tyne, NE1 4LP, England). *Virchows Arch.* [*Zellpathol.*] 18(3):225-242, 1975.

Kinetics of jejunal crypt cells were studied in 3-mo-old male Balb/c mice using tritiated thymidine (^{3}HTdR) labeling techniques in association with stathmokinetic studies with vincristine. Time parameters were determined by FLM experiment; 49 mice were injected i.p. with ^{3}HTdR, 1 μCi/g, and were killed thereafter. The mean cell cycle time (T_c) was 12.42 hr and the duration of DNA synthesis was 7.61 hr. A T_c of 11.9 hr was observed with a stathmokinetic technique using vincristine. The growth fraction, 0.61, calculated from cycle parameters and from the labeling index was compared to a value of 0.65 estimated from a labeling distribution curve. The mitotic duration was found to vary with cell population. The duration of mitosis for a whole crypt was 0.86 hr, between 0.8 and 1.2 hr for the proliferative compartment and somewhat shorter for basal cell positions. Apparent T_c were longest in the basal cell positions. The crypt migration rate, calculated from a cumulative birth rate curve, was 1.48 cell positions/hr, compared with 1.8 cell positions/hr as measured from movement of the 50% peak value on the labeling index distribution curve with time after ^{3}HTdr treatment. The crypt cell production rate, calculated from microdissected, squashed crypts, was 14 cells/crypt/hr. The total crypt population was 282 cells, of which 175 were proliferative. In some instances, the experimental results were compared with values previously published for mouse jejunal crypt cells.

6598 CELL POPULATION KINETICS IN THE RAT JEJUNAL CRYPT. *(Eng.)* Wright, N. A.; Al-Dewachi, H. S.; Appleton, D. R.; Watson, A. J. (Dept. Pathology and Medical Statistics, Univ. Newcastle upon Tyne, Newcastle upon Tyne, England). *Cell Tissue Kinet.* 8(4):361-368, 1975.

Autoradiographic techniques with tritiated thymidine (i.p. injection of 0.5 μCi/g) and a stathmokinetic technique with vincristine were employed to study the cell kinetics (including crypt cell production rate) in the jejunal crypt of 3-mo-old male Wistar rats. The migration rate of the 50% peak on the labeling index distribution curve 9 hr after administration of tritiated thymidine was 1.43 cell positions/hr. This was compared with the maximum value reached from a cumulative birth rate curve of 1.78 positions/hr. The product of the mean number of cells in the crypt column, 32.9, and in the column count (measurement made by counting ≅ 100 circular crypt cross sections), 22.3, gave an estimate of the total crypt population of 734 cells/crypt, compared with 650 estimated from direct observation of squashed, microdissected crypts. The mean number of mitoses/crypt was 22.5. The crypt cell production rate was 32 cells/hr; this value was confirmed by two independent techniques. The crypt growth fraction, calculated from the duration of phases of the cell cycle and the labeling index, was 0.62 compared to 0.61 found from the labeling index distribution curve. As assessed from crypt squashes, there were 402 proliferating cells/crypt.

6599 CELL SURFACE IMMUNOGLOBULIN. XIV. SYNTHESIS, SURFACE EXPRESSION, AND SECRETION OF IMMUNOGLOBULIN BY PEYER'S PATCH CELLS IN THE MOUSE. *(E.)* Vitetta, E. S.; McWilliams, M.; Phillips-Quagliata, J. M.; Lamm, M. E.; Uhr, J. W. (Univ. Texas Southwestern Medical Sch., Dallas, Texas 75235). *J. Immunol.* 115(2):603-605, 1975.

Peyer's patch cells were studied to determine whether presence of a δ-chain accounted for heavy-chain deficits (surface and intracellular) observed by immunofluorescence. Peyer's patches from BALB/c mice were radioiodinated and cultured *in vitro* with ^{3}H-leucine. Cells and medium were separated by centrifugation. The cells were lysed and the lysates dialyzed. Both lysates and secretions were centrifuged and the supernatants treated with rabbit anti-μ, anti-α, and anti-γ, polyvalent anti-Ig (μ, γ, α, κ, λ) or rabbit antibacteriophage ϕ x 174 (anti-ϕx) (control) and goat anti-rabbit Ig. Precipitates were subjected to electrophoresis. Neither IgG nor IgA was detected on the cell surface. In five experiments IgM constituted 5-15% of the total surface Ig. The most prominent heavy chain, precipitated by polyvalent serum only, had an approximate molecular weight of 68,000. Like the human δ-chain it was prevalent on the cell surface but not in the serum, was susceptible to proteolysis, was about 15% carbohydrate, and did not react with μ, γ, or α. In addition, both the δ-chain and the prominant heavy chain had similar molecular weights of both the assembled molecules and the intact heavy-chain. IgD constituted 85-95% of the total labeled Ig on the cell surface. An additional peak of molecular weight 40-45,000 was precipitated by most antisera and the control. Electrophoresis of the cell secretions showed identical patterns to those of the cell lysates. The δ- and μ-chain peaks were sharp, but the α-chain was heterogeneous. Anti-Ig precipitated an additional heavy chain peak of about 48,000 m.w. Labeling failed to yield a heavy chain with a molecular weight corresponding to that of an intact δ-chain. It is concluded that the δ-chains probably account for the heavy chain deficit on Peyer's patch cells.

6600 CHOLINERGIC INNERVATION OF THE GASTRIC WALL OF THE CAT. *(E.)* Kyosola, K.; Veijola, L.; Rechardt, L. (Dept. Anatomy, Univ. Helsinki, Finland). *Histochemistry* 44(1):23-30, 1975.

Morphologic patterns in the intrinsic cholinergic innervation of the gastric wall of the cat were studied. Sections of gastric wall were excised from anesthetized cats. Tissue was subjected to immersion fixation, perfusion fixation, or perfusion and subsequent immersion. Cholinesterases were demonstrated by one of two thiocholine techniques: Gomori's modification of the Koelle-Friedenwald technique or the direct-coloring copper-ferrocyanide method. Acetylcholinesterase-positive nerve fibers or small fascicles were observed in the muscularis externa of the pyloric region, running parallel to the stomach wall. A wide-meshed acetylcholinesterase-positive nerve network with large submucosal ganglia was observed in the serosa and in the subserosa. The general pattern of organization of the intrinsic cholinergic nervous apparatus of the fundic region was similar to that observed for the pyloric region. Duodenal tissue samples (controls) had acetylcholinesterase activity mainly confined to nerves in all layers of the duodenal wall. All smooth muscle layers of the gastric wall showed some degree of activity of the nonspecific cholinesterases; activity was most intense in the muscularis mucosae, moderate in the longitudinal muscle layer, and relatively weak in the circular muscle layer. It is concluded that the distribution of cholinesterase activity found indicates that the intrinsic cholinergic neural control concerns both the motor and secretory functions of the gastric mucosa.

6601 VEGETATIVE INNERVATION OF THE ESOPHAGUS. III. INTRAEPITHELIAL ENDINGS. *(Eng.)* Rodrigo, J.; Hernández, C. J.; Vidal, M. A.; Pedrosa, J. A. (Instituto Cajal, CSIC, C/Velázquez 144, Madrid 6, Spain). *Acta Anat. (Basel)* 92(2):242-258, 1975.

The vegetative innervation of the esophagus was studied in ten cats and three rhesus monkeys, with particular attention to the existence and morphology of the intraepithelial nerve endings. The esophagi were impregnated using the osmium tetroxide-zinc iodide technique. The nerve fibers reaching the neighborhood of the epithelium were shown to come from the distal portion of the submucous plexus. In the area of the cells of Langerhans, the fibers are mainly nonmyelinic, grouped together in bundles of different sizes, and surrounded by a common Schwann protoplasm. Towards the distal end, the nerve fibers begin to group together into thin nerve strings until they reach the basal layer, where they initially consist of two or three nerve fibers and later of completely isolated fibers, thus forming a subepithelial plexus in which all the fibers are nonmyelinic and completely varicose, some of them being associated with the blood capillaries in this area. The upper portion of the esophagus (next to the pharynx) and the lower portion (next to the cardia) show the densest penetration by nerve fibers, while the middle portion is penetrated only sporadically by an occasional fiber. In the upper portion, the bottoms of the grooves formed by the longitudinal folds show the greatest penetration of the basal surface by nerve fibers. In the middle portion, the fibers may penetrate at any point in the basal surface; in the lower portion, penetration is generally through the papillae formed by the epithelial covering in this area. The fibers are thin and delicate through their epithelial course and are probably directly attached to the epithelial cell bodies. The nerve fibers within the epithelium end freely in the spaces between the epithelial cells not far from the basal layer or, more frequently, near the lumen of the viscera. The morphology of the terminal ends varied considerably and was not associated with their position within the epithelium. The terminal portions of some of the fibers in the subepithelial plexus in the lower part of the esophagus form delicate laminar expansions which terminate the fiber or are inserted into the preterminal portion. These formations connect only with the cells forming the basal membrane of the epithelium and their endings generally assume a glomerular aspect. No neuroepithelial cells were observed in conjunction with the terminal apparatus. The data suggest that the nerve fibers within the mucous epithelium of the esophagus are solely of a sensory character.

6602 ELECTRONMICROSCOPIC OBSERVATIONS ON THE EFFECTS OF ORALLY ADMINISTERED ASPIRIN AND ASPIRIN-BICARBONATE MIXTURES ON THE DEVELOPMENT OF GASTRIC MUCOSAL DAMAGE IN THE RAT. *(E.)* Rainsford, K. D. (Univ. Tasmania, Medical Sch., GPO Box 252C, Hobart, Australia 7001). *Gut* 16(7):514-527, 1975.

The effects of aspirin (50-200 mg/kg p.o.) and an equimolar mixture of aspirin (200 mg/kg p.o.) with sodium bicarbonate on the fine structure of the gastric mucosa were studied in starved and nonstarved male hooded Wistar rats. The animals were killed 10 min to 5 hr after drug administration. The glandular mucosa was treated with formaldehyde and/or glutaraldehyde fixatives and examined by electron microscopy. In some experiments, the stomachs of rats anesthetized with pentobarbital sodium were perfused with fixative *in situ* prior to sectioning. Aspirin alone produced focal erosions in the corpus and body of the stomach of the fasted animals with evidence of bleeding in and around the eroded areas; the erosions were first evident 1 hr after treatment. Most of the damage occurred in the middle of the greater curvature of the corpus, and the damage was reduced in animals given lower doses of aspirin. Very little if any damage was produced by aspirin alone in the nonfasted animals or by aspirin plus bicarbonate in the fasted animals. Within 10 min after aspirin administration in the fasted rats, the surface mucosal layer assumed a whitish appearance and showed extensive sloughing. Extensive mucosal edema was observed in the starved animals given 150 or 200 mg/kg of aspirin alone, the degree of edema being reduced after 50 mg/kg of aspirin alone, aspirin plus bicarbonate, or 200 mg/kg aspirin in the nonfasted rats. The blood vessels in the stomach were extensively swollen in all rats given aspirin. On a fine structural level, a temporal sequence of events involving direct physical exfoliation of mucosal cells and selective structural damage to the parietal cells followed by structural damage indicative of a disturbance in oxidative and biosynthetic functions in the cells near the developing erosions was observed after 200 mg/kg aspirin in the fasted rats. The data indicate that the presence of aspirin particles in intimate contact with the mucosa is important in the development of gastric damage.

6603 EFFECT OF pH ON BILE SALT INJURY TO MOUSE GASTRIC MUCOSA. A LIGHT- AND ELECTRON-MICROSCOPIC STUDY. *(E.)* Eastwood, G. L. (United States Naval Hosp., Philadelphia, Pa.). *Gastroenterology* 68(6):1456-1465, 1975.

The influence of pH on bile salt-induced gastric injury and the morphological mode of injury were studied. Taurocholate and glycochenodeoxycholate were used. Adult male Swiss mice received solutions by esophageal intubation. Mucosal injury was graded as normal (0), mild injury (1), moderate injury (2), and severe injury (3). Taurocholate at pH 1 caused mucosal injury even at concentrations of only 0.1 mM and at 2 min of exposure (mean grade of severity, 1.9). A light micrograph of this injury showed that almost all surface mucous cells were damaged. There was also a decrease in staining intensity, mottling of the nucleus, and, in some instances, there was cell disruption. The severity of injury was greater with increasing concentration or duration of exposure. Taurocholate had no injurious effect at pH 3, 5 or 7. At pH 1, the mucosal injury caused by glycochenodeoxycholate was less than that caused by taurocholate (2 mM bile salt for 15 min gave a mean grade of severity of 1.1). At pH 3, however, glycochenodeoxycholate produced mucosal injury of grade 1.3; no injury was produced at pH 5 or 7. Electron microscope studies of injuries showed clumping of the nuclear chromatin as being indicative of mild cell injury. Most severely injured cells were often disrupted and sometimes fragmented. It is concluded that the morphological effects of bile salts are not specific and may relate to the ability of the agent, whether it is a primary irritant or a hydrogen ion, to gain entry to the cell interior.

6604 THE EFFECT OF BILE AND OF SODIUM TAUROCHOLATE ON THE EPITHELIAL CELL DYNAMICS OF THE RAT SMALL INTESTINE.

(Eng.) Roy, C. C.; Laurendeau, G.; Doyon, G.; Chartrand, L.; Rivest, M. R. (Hôpital Sainte-Justine, Montreal, Canada). *Proc. Soc. Exp. Biol. Med.* 149(4):1000-1004, 1975.

The regulatory role of bile and bile acids on epithelial cell dynamics in bile fistula rats after biliary diversion and under a constant duodenal Na taurocholate perfusion was studied. Bile fistula was established by insertion of a cannula in the common duct, 5 mm distal to hepatic duct bifurcation in ten male Sprague-Dawley rats. The control group consisted of ten sham-operated rats. After 48 hr, the absence of bile from the intestinal lumen led to: a decreased proliferative cell pool (based on a decrease of the mucosal scraping DNA specific activity), reduced cell shedding and a 50% decrease of the labeling index in the ileum. Constant duodenal perfusion of Na taurocholate for 48, 60, 72 and 96 hr in animals with biliary diversion was associated with: deepening of crypts, decreased crypt to villus ratios and acceleration of epithelial cell migration rate on the crypt-villus units. The data suggest that bile and, in particular, bile acids constitute important regulatory factors influencing enterocyte proliferation, migration and loss.

6605 EFFECTS OF p-CHLOROMERCURIBENZENE SULFONATE UPON ULTRASTRUCTURE OF CANINE GASTRIC SURFACE CELLS.

(E.) Zalewsky, C. A.; Moody, F. G.; Simons, M. A. (Univ. Utah Medical Center, 50 North Medical Drive, Salt Lake City, Utah 84132). *Gastroenterology* 69(2):427-438, 1975.

The morphological events involved in acute gastric erosion formation were studied systematically in mongrel dogs of both sexes. Segments of the greater curvature of the stomach were removed from the fasted animals and placed in double lumen lucite chambers. The experimental side of the mucosa was bathed with 10 mM *p*-chloromercuribenzene sulfonate (PCMBS) in 0.14 M HCl or 10 mM PCMBS in 0.1 M Tris buffer adjusted to pH 7.8-7.9 with HCl and made isosmotic with mannitol. The control sides of the mucosa were bathed with 0.15 M HCl, 0.1 M Tris buffer-mannitol without PCMBS. The gastric mucosa was observed visually and the arterial blood pressure was monitored throughout the experiment. The exteriorized segments of stomach were removed at various intervals and examined autoradiographically and by electron microscopy. Exposure of the mucosal surface of the exteriorized fundic segments to PCMBS resulted in gross and microscopic structural changes. The first visible response after PCMBS in isosmotic HCl was an intense release of periodic acid-Schiff-stainable mucous. Within 2 min, radioactive PCMBS was found within cells along the entire depth of the gastric glands. At 15 min, the surface cells showed vacuolization of the cellular cytoplasm, dilation of the perinuclear and intercellular spaces, mitochondrial swelling, loss of microvilli, and plasmalemma irregularities. The tight junctions, Golgi apparatus, and mucous granules appeared unaltered. However, in advanced injury (30 min), the mucous granules became less dense and their membranes, which were normally smooth, became fragmented and convoluted. Necrotic parietal cells were extruded into the lumen. Damage only rarely extended into the deeper glandular and connective tissue areas. Although the changes were of the same morphological type whether the PCMBS was in acid or buffer solution, the changes induced by acidified PCMBS occurred more rapidly and involved a greater number of cells. It is likely that PCMBS alters the permeability characteristics of the plasma membrane facing the lumen and of that part of the membrane forming the lateral sides of the cells.

6606 EFFECT OF DIOCTYL SODIUM SULFOSUCCINATE ON STRUCTURE AND FUNCTION OF RODENT AND HUMAN INTESTINE.

(E.) Saunders, D. R.; Sillery, J.; Rachmilewitz, D. (Dep. Med. RG-20, Univ. Washington, Seattle, Wash. 98195). *Gastroenterology* 69(2):380-386, 1975.

The hypothesis that dioctyl sodium sulfosuccinate (DSS), an anionic detergent often described as a stool softener, blocks water absorption in the small and large intestines was studied in fasted, anesthetized male Sprague-Dawley rats. Jejunal, ileal, and colonic segments were created and infused with buffer (9.5 ml/min in the small intestinal segments and 0.75 ml/min in the colonic segments) and then with buffer containing DSS (0.1-2.0 mM). Net water transport was measured under steady-state conditions. To test whether the observations in rats were relevant to the human jejunum, segments of jejunum in three healthy men and one healthy woman were studied by the triple lumen tube technique; buffer or buffer containing DSS (0.5-1.0 mM) were infused into the fasted subjects and the jejunal contents were aspirated at various intervals. In the rats, DSS inhibited water absorption in all three segments of intestine, the degree of inhibition being linearly related to the $\log_{10}$ of the DSS concentration. Histologically, the jejunal segments appeared unchanged by DSS infusion, but the detergent (0.5-2.0 mM) did alter the histologic appearance of the surface absorptive cells of the colon. In the latter case, the cells were flattened and their brush borders were no longer readily seen; the number of cells involved increased with increasing DSS concentration. DSS (0.5 mM) also significantly depressed water absorption (by 80%) in the human subjects. The effect was reversible and sodium, potassium, and chloride moved in parallel with the net water transport. The data indicate that DSS could be regarded as a stimulant laxative.

6607 MAST CELL INCREASE IN THE DUODENUM AND KIDNEY OF MAGNESIUM-DEFICIENT RATS. *(E.)*

Veilleux, R. (Dept. Anatomy, Univ. Montreal, Quebec, Canada). *Lab. Invest.* 33(1):80-87, 1975.

The possible influence of magnesium deficiency on increasing the population of subepithelial intestinal and kidney mast cells was studied. Of 52 Sprague-Dawley rats, 30 were fed a magnesium-deficient diet, while 10 controls were fed normally. Two controls and six deficient rats were killed after one to five weeks, and pieces of duodenum and kidney were either fixed and stained with Alcian Blue-safranin or quenched in liquid nitrogen cooled monochlorodifluoromethane, freeze-dried, exposed to formalin vapor, and subjected to fluorescence microscopy. Six of the remaining rats were kept on the deficient diet for four weeks, given 100 mg/kg L-dopa i.p. and killed after 2 hr. The last six were normal diet rats given L-dopa. The deficient rats showed a marked increase in duodenal subepithelial mast cells beginning at two weeks. Their mast cells had a more intense yellowish fluorescence than control mast cells. Administration of L-dopa after the fourth week enhanced the fluorescence in both deficient and control rats. After two to three weeks of deficiency, at least a twofold increase of Alcian Blue-positive fluorescent cells could be seen in the lamina propria, which sometimes lined up at the base of the epithelium. In all cases the epithelium itself was devoid of these cells. In the kidney, mast cells were extremely rare or absent in the controls by both Alcian Blue and formalin-induced fluorescence. L-dopa did not disclose any mast cells. In the deficient rats, both staining techniques showed numerous mast cells restricted to the cortex. These were apparent after the second week, mostly in the intertubular spaces. Alcian Blue fluorescent mast cells were also seen in the glomeruli. The intertubular mast cells were sometimes associated with local fibrous proliferative activity, or squeezed into the thin connective tissue sheath surrounding each tubule. The fluorescence ranged from yellow to green, usually contrasting with the intense yellow of the normal mast cells of the hilum and capsule. L-dopa markedly increased the intensity of fluorescence of all mast cells. It is concluded that magnesium deficiency in the rat increases the intestinal subepithelial mast cell population and the kidney cortical tubular and glomerular mast cell population.

6608 MORPHOLOGICAL STUDIES OF THE RAT SMALL INTESTINE AFTER JEJUNO-ILEAL TRANSPOSITION.

(E.) Gronqvist, B.; Engstrom, B.; Grimelius, L. (Univ. Hosp., Uppsala, Sweden). *Acta Chir. Scand.* 141(3):208-217, 1975.

Changes in small bowel mucosa after jejuno-ileal transposition were studied by light and electron microscopy. Male Sprague-Dawley rats were divided into three groups of nine animals: 1) controls; 2) sham-operated; and 3) jejuno-ileal transposed rats. Specimens of small intestine were taken at 2, 6 and 12 weeks postoperatively, from three rats in each group. Light, fluorescence, scanning electron and electron microscope examinations were made of four biopsy sites: distal to the proximal anastomosis, proximal and distal to the middle anastomosis, and proximal to the distal anastomosis. Weight increase in the third group 2 weeks postoperatively was lower than that of controls (33.4, 20.0 and 0.7% for groups 1, 2 and 3, resp.). At 6 and 12 weeks there was no significant difference between the groups (98.7, 96.0 and 87.5%, resp., at 12 weeks). No cell damage was seen in any group. Fluorescent microscopy showed the same number of cells and the same intensity of staining in all groups. There were no significant differences seen in the lengths and breadths of the villi, nor were changes seen in cytoplasmic organelles or microvilli. Quantitative studies showed that, at 2 and 12 weeks postoperatively, the villi of the ileum in the third group were significantly higher than those of the other two groups (19.7 and 58.4%, resp., at 2 and 12 weeks). The transposed jejunum also showed higher villi at 2 weeks (6.4%), but at 12 weeks the difference had decreased (0.1%). At 2 weeks the cell density in the transposed ileal segments in group 3 animals (229 cells/mm of basement membrane) was significantly higher than in the other two groups (209 and 199 cells/mm, resp., for control and sham-operated animals). At 12 weeks, the values for group 3 animals were significantly lower. From these data the mechanisms governing the development of hypertrophy in the transposed intestine are not clear. It is suggested that alterations in the intraluminal conditions, such as pH, pressure and possibly bacterial flora, may play a role.

6609 MORPHOLOGY IN THE CAT ILEAL MUCOSA FOLLOWING CONSTRUCTION OF AN ILEAL RESERVOIR OR TRANSPOSITION OF PATCHES TO DIFFERENT LOCATIONS.

(E.) Philipson, B. (Dept. Surgery, Sahlgrenska Inst., S-413 45 Goteborg, Sweden). *Scand. J. Gastroenterol.* 10(4):369-377, 1975.

Whether the structural changes recorded in human ileal reservoirs could be reproduced under similar conditions in cats, and the possibility of reversal of these morphological changes, was studied. Fasted and anesthetized domestic cats were given ileal reservoirs. The cats were also subjected to a variety of transpositions: an ileal patch to the cecum and later to the jejunum; an ileal patch to the urinary bladder; and an ileal segment to the sigmoid colon. At 1 to 3 months after surgery, the animals were sacrificed, and samples were taken from the reservoir, and from the ileum 5 cm proximal and 3 cm distal to the reservoir. The villi appeared to be shorter than in the normal ileum, and in most instances had leaf- and club-like shapes. Proximal and distal to the reservoir the villi were finger-like. This shape was restored when the patches were removed from the cecum to the jejunum. An inflammatory reaction was noted, which was especially pronounced in patches transposed to the urinary bladder. There was a significant decrease in villous height in the reservoir (353 μ) and distal to it (498 μ) compared to controls (760 μ); in the ileal patches transposed to the cecum (355 μ; control, 760 μ) and jejunum (546 μ; control, 750 μ). The villus height reduction was especially pronounced after transposition to the urinary bladder (266 μ; control, 760 μ). Increases in villus height were accompanied by an increased mitotic index. It is concluded that the structural changes seen in the human reservoir can be reproduced in animal models. These data suggest that the most important factor in the development of mucosal alterations is the irritating nature of the luminal contents.

6610 ELECTRON MICROSCOPIC STUDY OF CHRONIC PANCREATITIS INDUCED BY ADJUVANT INJECTION IN THE DOGS. *(E.)* Tsunoda, T.; Nakayama, I.; Taura, S.; Yoshino, R.; Ito, T.; Tsuchiya, R. (Nagasaki Univ. Sch. Med., Japan). *Nihon Rynsho Denshi Kenoikyo Gakkai-Shi* 7(3/4):345-346, 1974.

The histogenesis of chronic pancreatitis (induced in dogs) was studied by electron microscopy. Mongrel dogs (10-15 kg) received 1 ml of Freund's complete adjuvant by injection into the pancreatic parenchyma. The animals were sacrificed at 6, 9 and 24 hr, and 2, 4, 6, 8, 10, 20 and 30 days after injection. An increased number of lymphatic vessels with marked dilatation and intensive interstitial edema were noted at 6-24 hr, accompanied by the eduction of fibrin. Granulomatous lesions of various sizes formed in the interstitial tissue at 2-10 days. Each had an evident lumen without necrotic change in the central part, where fat and PAS stains were negative. At 6 days, the endothelial cells disappeared. The lymphatic wall was occupied by various inflammatory cells with granuloma formation. In the last stage of the experiment (20-30 days), some old granulomas still remained in part, but the interstitial tissue was mostly replaced by dense collagen fibers. This last stage closely resembled the histological picture found in human chronic pancreatitis.

6621 A MODIFIED FECAL EXCRETION TEST FOR ASSAYING INTESTINAL ABSORPTION OF ^{3}H-FOLIC ACID.

(E.) Elsborg, L. (Univ. Dept. Medicine, Aarhus Amtssygehus, DK-8000 Arhus C, Denmark). *Scand. J. Gastroenterol.* 10(2):207-208, 1975.

A folic acid absorption test is described, based on direct estimation of the nonabsorbed fecal fraction of an ingested dose of ^{3}H-folic acid. Fasting normal subjects (20) were fed 2 μCi (200 μg) of ^{3}H-folic acid and 0.4 μCi of $^{60}Co_2O_3$. Each of three 24-hr stool collections was placed on a sodium iodide crystal and only the fecal specimen containing the greatest amount of radioactivity was analyzed. Gas proportional counting was used to estimate ^{3}H activity after homogenization of the sample. The absorption of folic acid was calculated in percent of the amount ingested, given (1.00 - f) x 100%, where f is the unabsorbed fraction of folic acid. The counting efficiency for ^{3}H was found to be approximately 40%. In the subjects tested, fecal excretion of folic acid fitted well with a logarithmic normal distribution. The 0.95 range for f was 0.05 to 0.25. Accordingly, folic acid absorption ranges from 75% to 95% in normal subjects. It is suggested that this method may be useful for laboratories with less advanced equipment for radiochemical assay.

6622 PERMANENT BILE DUCT CANNULATION IN THE MONKEY. A MODEL FOR STUDYING INTESTINAL ABSORPTION.

(E.) Meszaros, J.; Nimmerfall, F.; Rosenthaler, J.; Weber, H. (Pharmaceutical Dept., Sandoz Ltd., 4002 Basel, Switzerland). *Eur. J. Pharmacol.* 32:233-242, 1975.

An experimental model for studying the intestinal absorption and biliary excretion of drugs and their metabolites is described. Cannulas of silicon rubber were inserted into the common bile duct up to the entrance of the cystic duct and through the stomach wall and the pylorus into the duodenum (to the entrance of the common bile duct) in 50 male rhesus monkeys. The cannulas were fixed at the point of insertion and the protruding portions were cut and joined to a plexiglass U-tube end-piece; when the animals were not being tested, the two tubes of the end-piece were joined by the U-tube, thereby giving the animals complete freedom. Postoperatively, the animals showed uneventful recovery and remained in normal condition. However, in over 90% of the animals, the catheter system was rejected after 8 or more wk of implantation and shunts were formed for the passage of bile around the point of insertion; this had no apparent detrimental effect on the animals. The specific gravity of the liver bile remained normal postoperatively and BSP tests for liver excretory function yielded values similar to those found in intact monkeys. Among the bile fistula animals, those with low k^{1}-values for BSP elimination showed the highest specific activity levels for alkaline phosphatase, SGOT, SGPT, and glutamate dehydrogenase; the specific activities of these enzymes were similar to those in 23 intact monkeys. Absorption tests carried out in nine bile fistula animals after intraduodenal ergotamine tartrate infusion showed a 96% average recovery of the applied dose and a mean intestinal absorption of 45% of the administered dose; the tests showed satisfactory reproducibility in the same animals over periods of 2 to 36 wk. This model appears to be well suited to studying the intestinal absorption of drugs which are excreted primarily in the bile. By sparing the animals the stress and discomfort of continuous chair sitting during repeated experimentation, it was possible to maintain them in a fit and near-normal condition throughout the study.

6623 PROPERTIES OF GLYCEROL-^{75}SE-TRIETHER: A LIPID-SOLUBLE MARKER FOR THE ESTIMATION OF INTESTINAL FAT ABSORPTION.

(E.) Hoving, J.; Valkema, A. J.; Wilson, J. H. P.; Woldring, M. G. (Univ. Hosp., Groningen, Netherlands). *J. Lab. Clin. Med.* 86(2):286-294, 1975.

The properties of a ^{75}Se-labeled glycerol triether were investigated in rat (Wistar stain, 180-200 g) experiments designed to test this substance as a nonabsorbable marker for measuring intestinal fat absorption. ^{131}I-triolein was used as tracer fat, and absorption was calculated using the isotope balance and isotope ratio methods. A mean of 99.4% of the 10 mg ^{75}Se-triether dose was recovered in the feces during the seven-day collection period. The separation of the lipid extract of the stools on TLC (thin-layer chromatography) revealed several ^{75}Se-containing compounds, of which one had the same mobility pattern as ^{75}Se-triether. Nonabsorbability of this compound was almost complete with a 98.2% recovery. All rats survived the experimental period with no significant weight gain, hematological, blood chemistry, or histological changes. No significant difference was noted when the amount of marker was increased. Comparison of methods gave correlation coefficients of 0.99 and 0.89 and regression coefficients of 1.02 and 0.99 depending on the time elapsed from time of administration (0-12 hr and 12-24 hr, resp.), showing that the marker moves through the gastrointestinal tract at the same rate as fat. If marker and test fat are given in a single dose, the estimation of fat absorption from the random stool sample is valid only if the marker/test fat ratio in feces is influenced exclusively by absorption of fat. The simplicity of the ^{75}Se-triether estimation in feces is a major advantage over other lipid-soluble markers and may provide a reliable and rapid test for estimation of intestinal fat absorption in man.

6624 SODIUM CHLORIDE REFLECTION COEFFICIENT IN RABBIT GALL BLADDER.

(E.) Monticelli, G.; Celentano, F.; Torelli, G. (Inst. General Physiology Physics, Univ. Milan, via Mangiagalli 32, 20133 Milano, Italy). *Biochim. Biophys. Acta* 401(1): 41-50, 1975.

The relation between volumetric flow and its driving forces, containing the Staverman reflection coefficient, was tested for sodium chloride in rabbit gallbladder and the reflection coefficient was evaluated. Everted gallbladders were perfused; the volumetric flow was measured gravimetrically. Experiments were performed with 15 gallbladders, varying sucrose concentration in a mucosal bathing solution between 0 and 200 mM, while the serosal solution (118.4 mM of NaCl, 25 mM of $NaHCO_3$, 4.7 mM of KCl, 2.5 mM of $CaCl_2$, 1.2 mM of KH_2PO_4 and 1.2 mM of $MgSO_4$, type A) remained unchanged. There was a linear dependence of the volumetric flow (J_v) on sucrose osmotic pressure difference in the concentration range of 0 to 80 mM. The permeability coefficient (L_p) in this range was 0.507×10^{-11} $cm^3 \times dine^{-1} \times s^{-1}$. Gallbladder permeability at higher sucrose concentrations decreased to reach a steady value at 0.124×10^{-11} $cm^3 \times dine^{-1} \times s^{-1}$ above 100 mM of sucrose. Negative $\Delta\pi_s$ (the partial osmotic pressure difference of solute S in the two compartments) values were obtained by lowering NaCl concentration in the outside solution, while these values were positive when the salt concentration was increased in the same solution. Volumetric flow was linearly related to $\Delta\pi_s$ and $\Delta\pi_i$. The mean reflection coefficient was 0.60, and the apparent reflection coefficient was found to depend on experimental conditions. It is concluded that a measure of membrane specificity for a species which is both actively and passively transported can be obtained only by accounting explicitly for the active transport contribution to volumetric flow.

6625 STUDIES OF GASTROINTESTINAL INTERACTIONS. VII. CHARACTERISTICS OF THE ABSORPTION PATTERN OF SUGAR, FAT AND PROTEIN FROM COMPOSITE MEALS IN MAN. A QUANTITATIVE STUDY.

(E.) Johansson, C. (Dept. Medicine and Gastroenterology, Karolinska Inst., Stockholm, Sweden). *Scand. J. Gastroenterol.* 10(1): 33-42, 1975.

The characteristics of carbohydrate, fat and protein absorption from composite meals during transit through the upper intestine were studied. Intubated healthy volunteers received 300 ml of two liquid test meals on different occasions. The first meal contained 3.6 g of protein/100 ml, 5.9 g of corn oil/100 ml, 5.1 g of lactose/100 ml and 10 g of glucose/100 ml. The standard test meal was the same, excluding the glucose. Polyethylene glycol (3 g/100 ml) was used as a marker. An average of 75% of the emptied amounts of sugar and 80% of the emptied fat and protein was absorbed during transit through the proximal 70 cm of the intestine. Differences in the absorption patterns between the two meals were recorded, resulting from their different intragastric behavior and gastric emptying patterns. Within the first hr significantly higher amounts of fat and protein were absorbed after the glucose-free than after the glucose-containing meal, whereas from the latter most of the glucose was absorbed early after ingestion. The absorptive capacity of the investigated segment was not exceeded for any component of the meals, owing to compensatory mechanisms by which the gastric emptying rate was inhibited and the transit time through the segment prolonged. The efficiency of sugar absorption was related to the transit time through the segment, in that a constant fraction was eliminated from the intestinal lumen/min increase of the mean transit time. The net endogenous contribution of protein and fat at the exit of the segment amounted to an average of 3.0 g protein and 1.2 g fat during 3 hr. These data suggest that the absorption rate is determined by the gastric emptying rate, which is in turn regulated by limiting factors released after absorption of the nutrient into the mucosal cell.

6626 INTERACTION OF AMINO ACIDS, PEPTIDES AND PEPTIDASES IN THE SMALL INTESTINE.

(E.) Cheeseman, C. I.; Smyth, D. H. (Dep. Physiol., Univ. Sheffield, England). *Proc. R. Soc. Lond. (Biol.)* 190(1099):149-163, 1975.

The effects of various amino acids, peptides and peptidases on intestinal absorption were studied in Sheffield rats. Everted sacs prepared from the combined jejunum and ileum were shaken for 30 min in bicarbonate saline solution containing β-alanine, L-alanine, L-proline, L-methionine, D-methionine, L-leucine, L-histidine, glycyl-L-leucine, L-leucylglycine, glycylglycine, D-leucyl-glycine, L-leucyl-L-alanine, and/or cobalt chloride; in some experiments, part of the Na in the bicarbonate saline was replaced by choline chloride. In another set of experiments, the combined jejunal-ileal segments were homogenized and the resulting suspension was shaken with bicarbonate solution containing the above-mentioned substances. The hydrolysis of glycylglycine by the intestinal homogenates was significantly inhibited by all amino acids tested except L-proline and L-alanine, L-histidine being by far the most effective inhibitor. Glycyl-L-leucine hydrolysis was also significantly inhibited by L-leucine, L-methionine, and L-histidine, while all amino acids tested except L-histidine significantly stimulated L-leucylglycine hydrolysis; in the latter case, L-histidine was a strong inhibitor. Similar results were obtained with the everted sacs. There was no evidence of competition between amino acids and dipeptides for an entry mechanism, but there was evidence for competition between different dipeptides. Cobalt caused stimulation of the dipeptidases in the homogenates but not in the everted sacs, which suggested that the dipeptidase was not accessible to cobalt in the intestinal lumen. The entry process of D-leucyl-glycine into the intestine showed evidence of saturation kinetics and was inhibited by reduction of the Na concentration in the bicarbonate solution. The results indicate that the terminal stage of digestion involves intracellular hydrolysis rather than contact hydrolysis, and point to a specific mechanism for peptide entry into the enterocyte from the lumen of the intestine.

6627 UPTAKE OF TAUROCHOLIC ACID INTO ISOLATED RAT-LIVER CELLS.

(E.) Schwarz, L. R.; Burr, R.; Schwenk, M.; Pfaff, E.; Greim, H. (Institut fur Toxikologie der Eberhard-Karls-Universitat Tubingen, D-7400 Tubingen, Wilhelmstrasse 56, Federal Republic of Germany). *Eur. J. Biochem.* 55(3):617-623, 1975.

The uptake of taurocholic acid into isolated rat liver cells was studied to further characterize the processes involved. Liver cells isolated from male Sprague-Dawley rats were incubated in a suspension containing 60 nCi of [^{14}C]taurocholate/ml of incubation medium and various concentrations of unlabeled taurocholate. Adsorption of taurocholate to the cell surface was terminated in less than 15 sec. A saturation constant of 0.55 mM and a total binding capacity of 3.8 nM/mg of cell protein were determined. The rate of uptake of taurocholate followed Michaelis-Menten kinetics, with the K_m equal to 19 μM and V equal to 1.7 nM/mg of protein/min. There was a broad pH optimum observed for uptake between pH 6.5 and 8.0. The activation energy amounted to 29 kcal/M. At high taurocholate concentrations (10 and 50 μM), an unusual upward bend was observed in the Arrhenius plot at lower temperatures. Taurocholate uptake was completely inhibited by taurochenodeoxycholate (K_i = 9 μM) and was noncompetitively inhibited by BSP (K_i = 3 μM). At physiological taurocholate concentrations, a 200-fold intracellular accumulation of taurocholate was observed. Uptake was inhibited by about 75% by either antimycin A, carbonylcyanide *m*-chlorophenylhydrazone or ouabain. Replacement of extracellular Na^+ by either K^+ or sucrose resulted in a 75% decrease of uptake. It is concluded that taurocholate uptake is a carrier-mediated process. It is further suggested that the energy for intracellular accumulation is made available by cotransport of Na^+.

6628 EFFECT OF DIET AND MICROBIAL FLORA ON INTESTINAL ABSORPTION OF SODIUM TAUROCHOLATE IN GERM-FREE RATS. *(E.)* Riottot, M.; Sacquet, E.; Mejean, C.; Leprince, C. (Laboratoire des Animaux sans Germes, C.N.R.Z., Jouy-en-Josas 78350, France). *Nutr. Rep. Int.* 12(1):1-7, 1975.

The effects of diet and microbial flora on the rate of intestinal absorption of sodium taurocholate were studied in germfree (axenic) and conventional (holoxenic) rats. The rats were maintained on a semi-synthetic diet containing no cholesterol or on a commercial diet containing 90 mg of cholesterol/100g of food. Segments of the small intestine were perfused with solutions of sodium taurocholate $(2,4\text{-}^3H)$ or $(4\text{-}^{14}C)$ and absorption was determined using liquid scintillation spectrometry. The perfusion method of Kimura was used to study absorption across the jejunum and ileum, while the perfusion method of Schiff was used to study absorption across the ileum only. The rate of absorption across the jejunum increased with increases in the amount of taurocholate in the perfusate; the augmentation was proportional to the taurocholate concentration in the rats given the commercial diet, but tended to be greater at the highest concentration (25 mM) in the rats given the semi-synthetic diet. Using Kimura's technique, the absorption rate was found to be higher in the ileum, where it increased considerably with increasing sodium taurocholate concentration. The absorption rate was not significantly affected by the presence or absence of intestinal microflora, but was much higher in the animals fed the commercial diet than in those fed the semi-synthetic diet. The results obtained using Schiff's technique were similar, but the absorption rates were lower and increased more slowly with increasing taurocholate concentration than was observed with Kimura's technique. The results suggest that the digestive tract microbial flora change the intestinal bile salt pool by mechanisms other than a variation in the bile salt absorption rate. It is also hypothesized that food cholesterol is responsible for the increase in the bile salt pool and absorption rate in the rats fed the commercial diet.

6629 EFFECT OF PARENTERAL ACETAZOLAMIDE ON INTESTINAL ABSORPTION OF SALT AND WATER IN MAN. *(E.)* Gerson, C. D.; Cohen, N.; Finkel, M.; Janowitz, H. D. (Mount Sinai Sch. Medicine, City Univ. New York, N.Y.). *Proc. Soc. Exp. Biol. Med.* 149(4):950-952, 1975.

The effect of i.v. acetazolamide administration on jejunal absorption was studied in man. After an overnight fast, six volunteers had a triple lumen tube inserted just beyond the ligament of Treitz. The proximal jejunum was infused with isotonic saline (154 mEq/ml at 9.5 ml/min). Polyethylene glycol (1.0%) was used as a dilution indicator. At the time infusion began, i.v. infusion was also started using 5% aqueous glucose. After 1 hr for equilibration and a second 1 hr period for a control study, acetazolamide was added to the i.v. perfusate (75 mg/kg) and infused for a 2-hr period. Measurements were taken during the second hr. During the two study periods, proximal and distal aspirates were collected at 1 ml/min. Proximal and distal collecting ports were separated by 30 cm. Aspirate determinations were made for water, sodium, chloride and bicarbonate flux. Each subject absorbed less water during the experimental than the control study period. The difference in mean values for the two periods (1.40 and 0.18 ml/cm/hr, resp.) was significant. Sodium absorption was reduced in five subjects, and chloride absorption dropped in all from means of 0.331 to 0.049 during perfusion of the drug. Mean bicarbonate concentration rose from 5.3 to 5.6 mEq/l, an insignificant change. It is concluded that i.v. acetazolamide has an inhibitory effect on jejunal absorption of sodium, chloride and water.

6630 PROPERTIES OF $(Na^+ + K^+)$-ACTIVATED ATPase IN RAT LIVER PLASMA MEMBRANES ENRICHED WITH BILE CANALICULI. *(E.)* Boyer, J. L.; Reno, D. (Dept. Medicine, Univ. Chicago, 950 E. 59th St., Chicago, Ill. 60637). *Biochim. Biophys. Acta* 401(1):59-72, 1975.

The properties of ATPase were evaluated with reference to the possible role of $(Na^+ + K^+)$-activated ATPase as a determinant of bile salt-dependent canalicular secretion in the rat. Membranes enriched with bile canaliculi were isolated from the hepatocytes of male albino Sprague-Dawley rats and optimum conditions for assaying $(Na^+ + K^+)$-activated ATPase were established. Enzyme marker studies of plasma membrane fractions revealed minimal contamination with non-plasma membrane material. The protein yield averaged 0.32 mg of protein/g of liver. Membrane $(Na^+ + K^+)$-activated ATPase activity was reproducible, and remained stable at 5 C. There was a linear relation between protein concentration and enzyme product over a 50 to 200 g protein range. When the sodium and potassium ion concentrations were varied, activity increased with $\mathrm{Na^+}$ concentrations up to 150 mM, but diminished at 200 mM. Increases in $\mathrm{K^+}$ concentrations above 5 mM had no effect. Imidazole was found to be the preferable buffer for assay of $(\mathrm{Na^+} + \mathrm{K^+})$-activated ATPase activity and the optimum pH was 7.8, while $\mathrm{Mg^{2+}}$-activated ATPase activity was most active at pH 8.0. Optimal specific activities of $(\mathrm{Na^+} + \mathrm{K^+})$- and $\mathrm{Mg^{2+}}$-activated ATPase activity occurred with $\mathrm{Mg^{2+}}$ concentrations between 1.0 and 2.5 mM. Higher $\mathrm{Mg^{2+}}$ concentrations resulted in diminished enzyme activity. Both the $\mathrm{Na^+}$ + $\mathrm{K^+}$ and the $\mathrm{Mg^{2+}}$-activated enzyme activities were temperature-dependent. Increasing concentrations of ouabain or scillaren progressively inhibited $(\mathrm{Na^+} + \mathrm{K^+})$-activated ATPase activity, but neither had any effect on $\mathrm{Mg^{2+}}$-activated enzyme activity. These data suggest that the $(\mathrm{Na^+} + \mathrm{K^+})$-activated ATPase activity in this membrane preparation are localized to the bile canaliculi, and are important to the secretion of bile salt-independent flow. Further investigations are recommended.

6631 EFFECT OF ASPIRIN ON IONIC MOVEMENT AND ACID HYDROLASE ACTIVITY OF EXPLANTS OF CANINE ANTRAL AND DUIDENAL MUCOSAE. *(E.)*

Himal, H. S.; Greenberg, L.; Boutros, M. I. R.; Waldron-Edward, D. (Div. Surgical Res., McGill Univ., Montreal, Quebec, Canada). *Gastroenterology* 69(2):439-447, 1975.

The activities of six acid hydrolases in antral and duodenal mucosae were determined before and after treatment with aspirin, and activity changes were correlated with mucosal barrier breakdown and changes in ion flux. Mongrel dogs were fasted 24 hr. The stomach was transected between the oxyntic gland area and the pyloric canal, and the antrum with intact blood supply was placed in a Lucite chamber. In five more dogs, the common bile duct was ligated and divided, and the mid-duodenum was devascularized, preserving the pancreaticoduodenal vascular arcade. The duodenum was transected between the major pancreatic portal duct and the pyloric sphincter, and the proximal duodenum was mounted in a Lucite chamber. Basal secretion was collected for 30 min, and test solutions of aspirin, hydrochloric acid and sodium chloride were instilled for 30 min and then aspirated. $\mathrm{Na^+}$, $\mathrm{K^+}$, $\mathrm{H^+}$, and $\mathrm{Cl^-}$ concentrations were determined. Mucosae from inside and outside the chamber and mucosae from control dogs were washed, homogenized, and assayed for cathepsin D, acid phosphatase, α or β-galactosidase, β-*N*-acetyl-glucosaminidase, and aryl sulfatase. Protein and soluble RNA were also determined. The hydrochloric acid-salt solution caused a net loss of $\mathrm{H^+}$ and $\mathrm{Cl^-}$ and a net gain of $\mathrm{Na^+}$ and $\mathrm{K^+}$. Aspirin treatment caused a much greater $\mathrm{H^+}$ loss and $\mathrm{Na^+}$ gain. Treatment also caused a rise in fluid volume secreted (from 0.00 to 0.20 ml/30 min by 120 min). Duodenal secretion rose from a basal value of 0.55 ml/30 min to 2.0 ml/30 min after acid-saline treatment. Aspirin treatment caused this value to fall to 1.82 ml/30 min after 120 min. Acid-saline caused great loss of $\mathrm{H^+}$. Net $\mathrm{H^+}$ loss was 1.8 $\mu\mathrm{Eq/cm^2}$ in the duodenum, as compared to 16,8 $\mu\mathrm{Eq/cm^2}$ in the antrum. $\mathrm{Na^+}$ gain was 14 times and $\mathrm{K^+}$ gain four times greater in the duodenum than in the antrum. Nonsedimenting proteins per gram of dry tissue was nearly equal in the antrum, fundus and duodenum; the fundus contained the most RNA. Cathepsin D activity was consistently higher in the stomach than in the duodenum. Treatment with aspirin and subsequent acid-saline washings increased the activities of five of the six acid hydrolases. It is concluded that aspirin acutely increases the activity of the acid hydrolases of the antrum and decreases that of the duodenum.

6632 INTESTINAL ABSORPTION OF FREE AND PROTEIN-BOUND DIETARY METHIONINE IN THE RAT. *(E.)*

Canolty, N. L.; Nasset, E. S. (Dept. Nutritional Science, Univ. California, Berkeley, Calif.). *J. Nutr.* 105(7):867-877, 1975.

Studies were undertaken to determine whether the rate of absorption of free dietary methionine differs from that of methionine incorporation in dietary protein. Isotopically-labeled compounds of methionine, L-[^{35}S]-methionine (^{35}S-Met), L-[^{75}Se]methionine (^{75}Se-Met), and 1 mCi/mg of selenomethionine were used as tracers in the test meals. Liquid or cooked and dried egg white was used in meals fed to male Long-Evans rats. Plasma and gastrointestinal contents were collected from 15 min to 16 hr after feeding. Plasma amino acids were determined after *ad libitum* diets containing free methionine. Protein-bound methionine in fresh egg white and free methionine left the stomach at the same rate, but protein-bound methionine in dried egg white was emptied from the stomach significantly more slowly than free methionine. Free methionine was absorbed from the intestine more rapidly than the protein-bound form. Concentrations and molar ratios of various amino acids in plasma changed briefly in response to methionine-supplemented test meals (0.4 g). Long-term changes were observed when methionine-supplemented diets were fed *ad libitum*. It is suggested that free dietary amino acids may induce adverse changes in plasma amino acid patterns.

6633 EFFECTS OF DIETARY LACTOSE AND A LACTASE PREPARATION ON THE INTESTINAL ABSORPTION OF CALCIUM AND MAGNESIUM IN NORMAL INFANTS. *(E.)*

Kobayashi, A.; Kawai, S.; Ohbe, Y.; Nagashima, Y. (Natl. Children's Hosp., Taishido 3-35-31, Setagaya Ku, Tokyo, Japan). *Am. J. Clin. Nutr.* 28(7):681-683, 1975.

The effects of dietary lactose and the administration of a lactase preparation on intestinal absorption of calcium and magnesium were studied. Fecal excretion of calcium and magnesium was measured in 15 healthy infants (age range, 2-8 months), divided into three groups receiving: a proprietary milk (eight infants); a lactose-free milk (four); and a proprietary milk plus a lactase preparation (three). The mean percent absorption of calcium in the first group was 60.4%, and of magnesium, 57.7%. Infants in the second group showed a significantly reduced mean absorption of both calcium and magnesium (36.5% and 39.3%, resp.) compared to the first group. The mean absorption of calcium and magnesium in the third group

(71.9% and 80.9%, resp.) was enhanced compared to the other two groups. A stimulating effect of dietary lactose on the intestinal absorption of both calcium and magnesium is suggested.

6634 ANALOG MODEL OF KINETICS OF CALCIUM IN HEALTHY SUBJECTS DURING ALIMENTARY Ca ABSORPTION.

(E.) Brodan, V.; Hajek, M.; Kocian, J. (Inst. Clinical Experimental Medicine, Prague, Kre 14622, Budejovicka 800, Czechoslovakia). *Comput. Biol. Med.* 4(3-4):257-267, 1975.

Short-term changes which take place under the acute transient impairment of calcium during alimentary Ca absorption were studied in healthy 20- to 22-yr-old men. Over the course of several months, all subjects were given ^{47}Ca as CaCl$_2$ by the i.v. (10 µCi in 1 ml saline) and p.o. (30 µCi in 100 ml of distilled water) routes; in addition, 30 µCi of ^{47}Ca was administered p.o. as CaCl$_2$ along with 10 mg/kg of nonlabeled Ca as CaCl$_2$ in 100 ml of distilled water. The subjects were fasted prior to Ca administration and blood was drawn 0-300 min after administration to determine the blood calcium level and plasma Ca activity. Based on the results, an analog model of the kinetics of calcium in the organism was constructed. The model was composed of a system of ordinary simultaneous differential equations which were resolved on an analog computer. The four-compartment model is characterized by six rate constants, by the ratio of plasma volume to the extravascular compartment of extracellular fluid, and by three regulatory relations. The first three rate equations describe the short-term kinetics of inactive Ca during alimentary absorption; the others describe the kinetics of ^{47}Ca under the same conditions. The regulatory relations between the digestive tract and plasma reduce the percentage of Ca absorption when its supply is increased. The proportional and integrating regulatory relations between the Ca pool in the extracellular fluid and the rapidly exchangeable Ca pool (particularly in the skeleton) affect the exchange of Ca between these two compartments. The back flow of Ca from the plasma into the bowel is important in the normalization of disturbed plasma calcium level after Ca injection or ingestion. This model is conceived as one of the steps leading toward an accurate mathematical analysis of the complex processes involved in the maintenance of calcium homeostasis in the organism.

6635 CALCIUM AND STRONTIUM TRANSFER THROUGH THE INTESTINAL WALL IN 6- AND 26-WEEK OLD RATS.

(E.) Stacic, M.; Gruden, N. (Institut za medicinska istrazivanja i medicinu rada Jugoslavenske akademije znanosti i umjetnosti, Zagreb). *Arh. Hig. Rada Toksikol.* 25(4):423-426, 1974.

The effects of age on the transport of calcium and strontium through different segments of the intestine were studied in 6- and 26-week-old female albino rats. Everted sacs were constructed from the duodenum, jejunum, and ileum of the fasted animals and were incubated with modified Krebs-Ringer solution containing 10 µCi of carrier-free ^{45}Ca or ^{85}Sr (only in the outside solution) and either calcium or strontium chloride (0.5×10^{-4} M). The activity of each marker was determined in the serosal and mucosal solutions and in the intestinal segments. Calcium and strontium transport in the duodenum was diminished in the older rats, the effect of age being most pronounced in the case of Ca. Strontium transport through the distal portions of the intestine was significantly greater than through the duodenum in the older animals. Although calcium was absorbed to a lesser extent than strontium in all animals, the difference was more pronounced in the younger rats. The retention of calcium and strontium was significantly greater in the duodenal wall of the younger rats; however, the biggest difference between calcium and strontium retention in the younger animals occurred in the duodenal segment. The data confirm previous observations that the absorption and transport of calcium in the duodenum diminish with age.

6636 CALCIUM ABSORPTION BY INTESTINE: STIMULATION IN VITAMIN D-DEFICIENT NEPHRECTOMIZED RATS BY Solanum glaucophyllum.

(E.) Walling, M. W.; Kimberg, D. V. (Harvard Medical Sch. Boston, Mass, 02215). *Gastroenterology* 69(1):200-205, 1975.

Vitamin-D deficient male Holtzman rats were used to study the effects of nephrectomy and a diet containing *Solanum glaucophyllum* on calcium absorption. A low-calcium diet was fed for seven weeks, and two days prior to death all rats were fed a low salt diet to minimize effects on renal insufficiency. Twenty-four hr prior to death the rats were subjected to either a sham operation or total bilateral nephrectomy. Immediately after surgery either 1.0 ml of isotonic saline or acqueous *Solanum* extract was given i.p. Duodenal calcium transport was studied *in vitro* using ^{45}C as tracer in modified Ussing-flux chamber apparatus. Plasma calcium, magnesium, phosphorus, creatinine, and alkaline phosphatase were measured. Prior administration of *Solanum* extract (250 mg dry leaf) increased active absorption 6.2-fold in sham operated, vitamin-D deficient rats and 4.5-fold in nephrectomized animals. Serosal to mucosal flux of calcium and tissue conductance was unchanged by any experimental condition. *Solanum* extract elevated plasma calcium, magnesium, and phosphorus levels but depressed alkaline phosphatase levels compared with controls. Nephrectomy increased plasma magnesium and creatinine but depressed calcium and alkaline phosphatase levels in both control and *Solanum*-treated animals. The data demonstrates that *S. glaucophyllum* leaf contains a water-soluble substance which stimulates active calcium absorption by the duodenum and can effect absorption without the influence of renal tissue. The biological action of *S. glaucophyllum* apparently bypasses the normal means of regulating calcium absorption.

6637 COMPARATIVE STUDIES OF THE INTESTINAL ABSORPTION OF (^{3}H)PTEROYLMONOGLUTAMATE AND (^{3}H)PTEROYLHEPTAGLUTAMATE IN MAN.

(E.) Godwin, H. A.; Rosenberg, I. H. (Baylor Coll. Medicine, Houston, Tex.). *Gastroenterology* 69(2):364-373, 1975.

The absorption of synthetic ^{3}H-pteroylheptaglutamate (folate) was studied quantitatively in 11 normal volunteers and compared with absorption of synthetic ^{3}H-pteroylglutamic acid (folic acid) absorption. After an overnight fast, a venous blood specimen was taken, and the bladder was voided. Each subject was given p.o. 0.6 µM of either one of the labeled folates. Venous blood samples were taken at 30 min and at 1, 2, 3, 4, and 5 hr. Total urine collections were taken at 0 to 4, 8 to 12, 12 to 24 and 24 to 48 hr. After the first 4 hr of testing, fasting was ended and 15 mg of unlabeled folic acid was given i.m. to flush absorbed folate from the tissues and to maximize urinary recovery. In three subjects, tests were repeated after 3 to 4 days. Urine was analyzed by chromatography and electrophoresis; radioactivity of urine and plasma was determined by scintillation counting. Following the dose of folic acid, total urinary excretion of radioactivity over 48 hr was 70.8%. After the dose of folate, urinary radioactivity excretion was 56.1%. Results were reproducible in two patients given repeated tests. Time patterns of urinary excretion of radioactivity were identical for both folic acid and folate. About 5% appeared during the first four hr. After flushing, 50% of the urinary radioactivity appeared during the following four hr. About 20% appeared after 8 to 12 hr, 15% after 12 to 24 hr, and 90% total for 25 hr. After 24 hr, excretion ranged from 1.4 to 19.6%. A second flush raised the excretion of folate, but not of folic acid. Mean stool excretion over three- or four-day collection periods were 37.7% for folate and 24.4% for folic acid. Elevated plasma radioactivity was detectable 30 min after the dose of either folic acid or folate. Peak activity occurred at 1 hr and 2 hr, resp. Flushing caused a marked rise from displaced extravascular folate, whichever drug was used. The label in the serum was attached to monoglutamyl folate. Presence of free folate was demonstrated by assay with *Lactobacillus casei*. Intact folic acid polyglutamates were not demonstrable in the serum. Analysis of urine showed that 67 to 85% of the radioactivity in 4 to 8 hr migrated with standard pteroylmonoglutamates. It is concluded that synthetic folate is absorbed efficiently, but not as well as synthetic folic acid.

6638 MECHANISM AND SITE OF SMALL INTESTINAL ABSORPTION OF α-TOCOPHEROL IN THE RAT.

(E.) Hollander, D.; Rim, E.; Muralidhara, K. S. (Dept. Medicine, Wayne State Univ., Detroit, Mich. 48201). *Gastroenterology* 68(6):1492-1499, 1975.

The mechanism of intestinal absorption of α-tocopherol and the regional differences of its absorption by the small intestine were studied using male Sprague-Dawley rats. Everted small bowel sacs were incubated in a micellar medium. The mean absorption rates of the vitamin at 300 µM incubation solution concentration by proximal, medial, and distal small bowel segments were 2.2, 3.4, and 2.0 nM/min/100 mg, resp. The rate of absorption was not changed by the addition of 2,4-dinitrophenol, sodium azide, or potassium cyanide to the incubation medium. A linear increase in the absorption rate was achieved by stepwise increase in incubation solution tocopherol concentration up to 1200 µM. In all experiments, the rate of absorption of the vitamin by the medial portion of the small intestine was significantly higher than the rate of absorption of the vitamin by the proximal and distal small bowel segments. Transmural transport of the vitamin into the serosal compartment did not occur. Accumulation of the vitamin in the submucosal lymphatic spaces was confirmed by autoradiographic examination of the tissue after incubation. It is concluded from these studies that the absorption of α-tocopherol by the rat small intestine is a passive diffusion process taking place at the highest rate in the medial portion of the small intestine.

6639 TRANSPORT OF AMYLASE ACROSS THE APICAL MEMBRANE OF THE PANCREATIC EXOCRINE CELLS. QUANTITATIVE ANALYSIS OF ZYMOGEN GRANULES.

(E.) Dandrifosse, G.; Simar, L. (Lab. General Comparative Biochemistry, Univ. Liege, Place Delcour, 17 B-4000 Liege, Belgium). *Pfluegers Arch.* 357(3/4):361-368, 1975.

A study is presented disproving the possibility that some types of zymogen granules, ready for secretion, are destroyed by homogenization or centrifugation processes, leading to the presence of amylase in the agranular fraction of the cell. Slices were prepared from the pancreas of pigeons which had been fed *ad libitum* or fasted for 24 hr. One slice was fixed for electron microscopy; the others were homogenized and centrifuged. The number of zymogen granules (N_v) and their surface density (S_v) were higher in slices derived from starved pigeons (315/mm^3 and 15 x 10^{-4} cm^2/cm^3, resp.) than the number in slices from fed animals (60/mm^3 and 1.8 x 10^{-4}, resp.). There was no significant difference noted in the isolated subcellular fractions compared to whole slices: 334 and 63/mm^3 for the N_v; and 12.7 x 10^{-4} and 1.6 x 10^{-4} cm^2/cm^3 for the S_v of fasted and fed pigeons, resp. These data support previous suggestions that amylase can be transported molecule by molecule across the intact apical membrane of pancreatic exocrine cells.

6640 TRANSPORT OF DEUTERIUM OXIDE ACROSS ISOLATED RAT SMALL INTESTINE.

(E.) Bywater, R. J.; Fisher, R. B.; Gardner, M. L. G. (Univ. Edinburgh Medical Sch., Teviot Place, Edinburgh, EH8 9AG, Scotland). *J. Physiol. (Lond.)* 249(3):591-600, 1975.

The transport of deuterium oxide from a luminal perfusate containing 1% D_2O was studied in isolated perfused intestinal segments from anesthetized female rats. The lumen was perfused with bicarbonate saline medium containing glucose (5 mg/ml, 28 mM). After allowing the luminal conditions to stabilize, serial collections of the serosal secretion were made over 2-min periods. The deuterium oxide concentrations in the secretion samples and luminal perfusate were determined, and the results were analyzed using a digital computer program. The kinetics of the appearance of D_2O in the intestinal secretion fitted well into a single exponential function, the steady-state concentration of D_2O in this secretion not differing significantly from the concentration in the luminal perfusate. The total tissue water contained D_2O at a concentration which averaged 5% lower than that in the luminal perfusate. There was no evidence to suggest discrimination in transport across the intestinal mucosa between H_2O and D_2O. The kinetics of wash-in of D_2O to the intestinal secretion indicated that the ratio of flux out of the lumen to reflux back into the lumen was 1.38:1.

6641 EFFECT OF ETHANOL ON SODIUM-DEPENDENT GLUCOSE TRANSPORT IN THE SMALL INTESTINE OF THE HAMSTER.

(E.) Dinda, P. K.; Beck, I. T.; Beck, M.; McElligott, T. F. (Hotel Dieu Hosp., Kingston, Ontario, Canada K7L 3H6). *Gastroenterology* 68(6): 1517-1526, 1975.

The effects of ethanol on the transmucosal potential difference, water and glucose transport, and intracellular electrolyte concentration of the small intestine were studied in isolated segments from female hamsters. Three series of experiments were performed. Intestinal preparations were all incubated in Krebs-Ringer bicarbonate solution containing 10 mM of glucose (control). Series 2 also contained 300 mM of ethanol (1.28 g/100 ml), and series 3, 450 mM of ethanol (2.07 g/100 ml). The presence of ethanol caused an inhibition of the net transport of water and glucose, a decrease in intracellular water content, and an increase in intracellular sodium and potassium concentrations. The intracellular glucose concentration, however, decreased in the presence of ethanol. In the series 3 experiments there was also a significant inhibition of transmucosal potential difference, estimated glucose metabolism and both unidirectional (mucosal to serosal and serosal to mucosal) fluxes of sodium. The net flux of sodium to the serosal side did not decrease significantly. It is suggested that the ethanol-induced reduction in glucose transport could be the result of an interference with the carrier-mediated coupled entrance of glucose and sodium across the brush border.

6642 CATECHOLAMINE EFFECTS ON CYCLIC AMP LEVELS AND ION SECRETION IN RABBIT ILEAL MUCOSA.

(E.) Field, M.; Sheerin, H. E.; Henderson, A.; Smith, P. L. (Harvard Medical School, Boston, Mass. 02215). *Am. J. Phys.* 229(1):86-92, 1975.

The effects of catecholamines on cyclic-AMP (cAMP) and on cAMP-mediated ion transport processes in rabbit ileal mucosa were studied. New Zealand white male rabbits weighing 2-3 kg were used as tissue source. The base-line cAMP level was not affected by epinephrine, norepinephrine, or isoproterenol. Propranolol did not enhance the lowering trend produced by epinephrine on theophylline-augmented cAMP levels indicating that adenylate cyclase-coupled β-adrenergic receptors are not present in significant numbers in ileal mucosa. An increase in cAMP level produced by cholera toxin was reversed by epinephrine and norepinephrine; this reversal was prevented by phenoxybenzamine. Epinephrine partially reversed the increase in cAMP levels produced by prostaglandin E_1 indicating that the inhibitory effect is nonspecfic. In the presence of epinephrine alone there was substantial and equal net absorptive fluxes of Na and Cl ions, a low short-circuit current (SCC), high conductance, and a residual ion flux close to zero indicating enhancement of NaCl absorption and inhibition of HCO_3 secretion. In the presence of theophylline, cAMP or cholera toxin, epinephrine produced a decrease in SCC and an increase in conductance. The effects of α-adrenergic stimuli on intestinal ion transport may not be primarily the result of changes in cAMP levels. Changes in ion transport cannot be safely inferred from changes in cAMP levels of whole mucosa and *vice versa*.

6643 EFFECT OF HORMONES ON PANCREATIC MACROMOLECULAR TRANSPORT.

(E.) Singh, M.; Webster, III, P. D. (Veteran's Administration Hosp., Augusta, Ga.). *Gastroenterology* 68(6):1536-1542, 1975.

The effects of acute and chronic administration of cholecystokinin-pancreozymin (CCK-PZ), pentagastrin and secretin on pancreatic macromolecular synthesis and secretion were studied *in vitro*. Pancreatic slices were prepared from male Sprague-Dawley rats. Pooled slices were pulse-labeled with L-[^{14}C]phenylalanine (10 μCi, 22 μM) and migration of ^{14}C-labeled proteins was studied by "chase" incubation for 15, 30, 60 and 120 min. After incubation of control and drug-treated pancreatic slices, subcellular particles were isolated by differential centrifugation. Specific activity of ^{14}C-labeled proteins was determined in subcellular fractions involved in transport and secretion of digestive proteins. CCK-PZ and pentagastrin, used *in vitro*, did not alter the intracellular transport of proteins, although secretion was enhanced. Chronic stimulation of the pancreas with CCK-PZ did not alter the rates of intracellular transport. It is concluded that secretin has no effect on the intracellular transport and secretion of pancreatic macromolecules in acinar cells.

6644 THE EFFECT OF OUABAIN ON ION TRANSPORT ACROSS ISOLATED SHEEP RUMEN EPITHELIUM.

(E.) Harrison, F. A.; Keynes, R. D.; Rankin, J. C.; Zurich, L. (Agricultural Res. Council Inst. Animal Physiology, Babraham, Cambridge, CB2 4AT England). *J. Physiol.* 249(3):669-677, 1975.

The electrical properties of sheep rumen epithelium were altered by ouabain treatment and changes in the unidirectional and net fluxes of Na, K, and Cl were studied. Epithelial strips were mounted in two identical chambers and bathed in unlabeled Ringer and ouabain solution for 30 min (until tissue and Ringer solution reached equilibrium). In the third 30 min period after ouabain treatment, the net flux of Na from the lumen to the blood side of the epithelium was reduced to zero (5×10^{-5} M or 10^{-4} M of ouabain), the net flux of K from the blood to the lumen was reduced from 0.34 to 0.13 μM/cm^2/hr (5×10^{-5} M of ouabain), and the net flux of Cl from lumen to blood went from 1.4 to 0.77 μM/cm^2/hr (5×10^{-5} M of ouabain). The results suggest the existence of a K and Cl pump which is independent of Na transport in sheep rumen epithelium.

6645 MERCURIAL PERTURBATION OF BRUSH BORDER MEMBRANE PERMEABILITY IN RABBIT ILEUM. *(E.)*

Stirling, C. E. (Univ. Washington Sch. Medicine, Seattle, Wash. 98195). *J. Membr. Biol.* 23(1):33-56, 1975.

The effects of organic mercury and p-chloromercuriphenyl sulfonic acid (PCMBS) on amino acid and sugar influx across the brush border, Na^+ permeability, and the ileal uptake of ^{203}Hg-PCMBS were studied *in vitro* using tissues from female New Zealand white rabbits. Both Hg^{++} and PCMBS at mM concentrations reduced the mucosal entry of sugars and amino acids to 80 to 90% of control values within several min. Based on the 50% levels of inhibition, Hg^{++} was 10- and 20-fold more potent than PCMBS in blocking sugar and amino acid influx, resp.; both systems were equally sensitive to Hg^{++}. The ileal accumulation of ^{203}Hg-PCMBS demonstrated a pattern of progressive uptake which showed no tendency toward saturation. This suggested appreciable epithelial entry with prolonged exposures (>30 min at 1 mM). At similar dose levels, Hg^{++} and PCMBS had no significant effect on mucosal Na^+ permeability. The inhibition of sugar and amino acid influx was not affected by washes in choline-salt solutions, but dithiothreitol (10 mM) reversed Hg^{++} and PCMBS inhibition by 40 and 100%, resp. Alanine and galactose influx kinetics measured at concentrations of 0 to 100 mM exhibited a linear or diffusional entry component in addition to the usual saturable component for both control and Hg^{++}-treated ileum. The presence of a diffusional term in the flux equation resulted in two sets of parameters giving nearly equal fits to these measurements. This ambiguity could be resolved by determining the change in diffusional entry with Hg^{++} treatment. A 20-min exposure to 0.5 mM of Hg^{++} resulted in an increase from 0.050 and 0.045 to 0.064 and 0.070 cm/hr in the coefficient of diffusional entry for alanine and galactose, resp. Thus, Hg^{++} appears to cause a decrease in J_{max} and little change in K_m for both transport mechanisms. This analysis has general bearing on kinetic measurements of transport in which passive fluxes are comparable to those mediated by specific pathways.

6646 ISOOSMOTIC TRANSPORT OF FLUID ACROSS THE HAMSTER SMALL INTESTINE IN THE PRESENCE OF PHLORIZIN-INDUCED INHIBITION OF SUGAR TRANSPORT.

(E.) Dinda, P. K.; Beck, M.; Beck, I. T. (Hotel Dieu Hosp., Kingston, Ontario, Canada K7L 3H6). *Can. J. Physiol. Pharmacol.* 53(3):375-382, 1975.

The effect of partial inhibition of active glucose transport on isoosmotic transport of fluid was studied in intestinal segments isolated from female hamsters. Each segment was incubated in Krebs-Ringer bicarbonate containing 10 mM of glucose and: 1) no other agent (isotonic control); 2) 5 x 10^{-5} M of phlorizin (isotonic); 3) 50 mM of mannitol (hypertonic control); and 4) 50 mM of mannitol plus 5 x 10^{-5} M of phlorizin (hypertonic). Incubations were carried out for 60 min at 37 C. The absorbate was isoosmotic with the mucosal solution in all groups. The addition of phlorizin to the isotonic mucosal solution caused a reduction in the concentration of glucose in the absorbate (57.7 mM and 37.6 mM, resp., for groups 1 and 2). Isotonic segments had a significantly higher concentration of sodium (121.1 mM) and potassium (4.0 mM) compared to isotonic controls (115.2 mM and 3.2 mM, resp.). The concentration of both glucose and the electrolytes increased in hypertonic solutions. The addition of phlorizin in group 4 caused a decrease in glucose concentration (41.8 mM) compared to the hypertonic control (66.2 mM). The presence of phlorizin or mannitol significantly depressed the potential difference (group 1, 10.7; group 2, 6.4; group 3, 8.9; and group 4, 5.8 mV). Glucose transport/g dry tissue was depressed in group 2 ($p < 0.05$). Glucose, fluid and electrolyte transport were significantly decreased in groups 3 and 4. The magnitude of inhibition in fluid and electrolyte transport produced by mannitol alone (49.2% for fluid, 44.2% for sodium, and 46.5% for potassium) was similar to that produced by mannitol and phlorizin together (44.4, 32.5 and 19.0%, resp.). These data suggest that phlorizin inhibits sodium movement through the electrogenic pathway, but increases the transport of this ion through the electrogenic route. It is further suggested that isoosmotic fluid transport is an inherent property of the small intestine.

6647 A Na^+-INDEPENDENT, PHLORETIN-SENSITIVE MONOSACCHARIDE TRANSPORT SYSTEM IN ISOLATED INTESTINAL EPITHELIAL CELLS.

(E.) Kimmich, G. A.; Randles, J. (Univ. Rochester, Sch. Medicine and Dentistry, Rochester, N.Y. 14642). *J. Membr. Biol.* 23(1): 57-76, 1975.

A monosaccharide transport system in addition to the active Na^+-dependent system characteristic of the brush border surface of vertebrate intestinal tissue has been identified in isolated chick (6-8 wk old) intestinal epithelial cells. The accumulation of ^{14}C-3-O-methylglucose (1 mM) by the isolated cells was studied as a function of time under conditions in which the cells were separated from the incubation medium by centrifugation or millipore filtration. The effects of Na^+, D-glucose, phlorizin (10-200 μM), phloretin (10-200 μM), valine (1 mM), leucine (25 mM), fructose, mannose, glucose, and/or 2-deoxyglucose (all sugars at 50 mM) on this accumulation were also studied. The data obtained after separation by centrifugation and millipore filtration were similar. A true unidirectional flux of 3-O-methylglucose in the isolated cells was demonstrated. It was dependent on Na^+, inhibited by phlorizin, and inhibited by the inclusion of glucose in the medium. The total Na^+-independent 3-O-methylglucose entry rate was inhibited by phloretin in concentrations as low as 10 μM, but this compound had no effect on the Na^+-dependent entry system. In contrast, phlorizin had no effect on the Na^+-independent system. Phloretin had no effect on the unidirectional flux of valine, although leucine inhibited the entry of valine by 85% under the same conditions. The phloretin-sensitive entry rate was inhibited by glucose and galactose, but not by ketohexose or fructose; xylose and mannose were mildly inhibitory, while 2-deoxyglucose was the most effective inhibitor studied. Phloretin selectively blocked the efflux of sugar from cells which had accumulated sugar to a steady state; thus, a normal steady-state sugar gradient of seven- to eight-fold was transformed to a new steady-state gradient of greater than eight-fold. The data indicate that the monosaccharide transport system functions only in a facilitative diffusion manner so that it moves monosaccharide across the cell membrane along a downward chemical gradient. The locus of the system is tentatively ascribed to the serosal cell surface, where it would serve for monosaccharide transfer between enterocytes and the lamina propria of the villi.

6648 PYRIDOXINE TRANSPORT ACROSS THE TURTLE, RAT AND RABBIT INTESTINES. *(Eng.)* Hajjar, J. J.; Nassar, K. (Sch. Med., American Univ. Beirut, Beirut, Lebanon). *Comp. Biochem. Physiol.* [*A*] 52: 389-393, 1975.

The intestinal transport of pyridoxine was examined *in vitro* using tissues from fresh-water turtles *(Testudo graeca)*, Sprague-Dawley rats, and rabbits. Turtle and rabbit tissues were mounted between two lucite chambers and equal concentrations of pyridoxine were placed in both the serosal and mucosal solutions; ^{3}H-pyridoxine was added to one side only and its rate of appearance on the opposite side was measured in the presence and absence of alanine. In other experiments, turtle mucosal strips were incubated for 2 min in solution containing labeled and unlabeled pyridoxine and ^{14}C-inulin, after which the ^{3}H and ^{14}C contents in the tissue and test solution were determined. The steady-state uptake of pyridoxine by turtle, rat and rabbit mucosal strips was simularly determined after 60 min of incubation in labeled and nonlabeled pyridoxine and ^{14}C-inulin. The mucosal-to-serosal and serosal-to-mucosal fluxes of pyridoxine were equal in the presence of equal low concentrations of pyridoxine in the serosal and mucosal solutions; at higher concentrations, however, the fluxes were not solely explainable on the basis of simple passive diffusion. The unidirectional fluxes of pyridoxine were more than two-fold greater in the turtle than in the rabbit and the fluxes were not influenced by the presence of alanine in the medium. The initial uptake rate of pyridoxine by the turtle mucosal strips was linear with physiological medium pyridoxine concentrations, and curvilinear with concentrations above 5mM. Pyridoxine did not accumulate in the epithelial cells of the turtle, rabbit, or rat intestine. The intracellular to extracellular distribution ratio and low vitamin concentration was close to unity, but at higher concentrations, the intracellular pyridoxine levels remained lower than the extracellular levels in spite of extended incubation periods. Amino acids had no effect on the steady-state uptake of pyridoxine by the epithelial cells in any species. The results indicate that pyridoxine at low concentrations is transported by simple passive diffusion, but that at higher concentrations the vitamin limits its own permeation through the cell membrane. The data do not support the possibility of a complete interdependence between transport of the vitamin and amino acids.

6649 EFFECTS OF SODIUM ON SOLUTE TRANSPORT BETWEEN COMPARTMENTS IN INTESTINAL MUCOSAL EPITHELIUM. *(E.)* Boyd, C. A. R.; Cheeseman, C. I.; Parsons, D. S. (Univ. Oxford, Dep. Biochemistry, South Parks Road, Oxford OX1 3QU, England). *Nature* 256(5520):747-749, 1975.

The effects of sodium on the transfer of solute between compartments in the intestinal mucosal epithelium were studied using a vascularly perfused preparation of frog intestine. Removal of Na from the vascular bed inhibited solute transfer into the blood and decreased the extracellular space. Addition of Na to the vascular perfusate increased the rate of efflux of intracellular 3-O-methyl-D-glucose (3-O-MeG) into the vascular bed. Furthermore, after Na-free perfusion of the lumen and vascular bed, the return of Na to the lumen increased the rate of efflux of 3-O-MeG from the cells into the vascular bed. The total quantity of 'intracellular' 3-O-MeG loaded into the cells from the circulation increased by 43% on addition of Na to the vascular perfusate. When the brush-border amino acid uptake systems were saturated with 10 mM of relevant amino acids, the removal of Na from the vascular perfusate resulted in a large, but reversible inhibition (67%) of the transfer of amino acids initially taken up in the form of peptide into the vascular bed. The uptake of peptide from the intestinal lumen was independent of Na in the lumen. 2-Deoxy-D-glucose (2-DOG) appeared at a faster rate in the effluent from the lumen than 3-O-MeG when the rate of appearance of the two compounds from constant vascular infusion was studied. A pulse of 10 mM glucose in the lumen resulted in a sudden increase in the appearance of both sugars, but the effect was proportionately 5-fold greater for 3-O-MeG. The subsequent addition of phlorizin to the lumen increased the rate of appearance of 3-O-MeG but had no effect on the movement of 2-DOG. It is concluded that in addition to its role in membrane transport, Na also expands extracellular spaces within the intestinal mucosa with consequential effects on the clearance of transported substrates from these spaces. The clearance may be forward into the blood stream or backward into the unstirred layer in the lumen. The requirement for Na for this purpose can be completely filled by its presence in the vascular bed, but only partially fulfilled by the addition of Na to the lumen when Na is absent from the vascular perfusate.

6650 EFFECT OF SUCROSE FEEDING ON THE INTESTINAL TRANSPORT OF SUGARS IN TWO STRAINS OF RATS. *(E.)* Reiser, S.; Michaelis, IV, O.; Putney, J.; Hallfrisch, J. (Nutrition Inst., Agricultural Res. Service, United States Dept. Agriculture, Beltsville, Md. 20705). *J. Nutr.* 105(7):894-905, 1975.

The effect of high-sucrose diets on the rate of intestinal absorption of dietary sugars in Wistar and carbohydrate-sensitive BHE rats was studied. Control rats were fed a stock diet and experimentals, a diet containing 65% sucrose. Determinations were made of immunoreactive insulin from sera obtained after 17 days. After 7-12 weeks of the diet, rats were killed and small intestines and livers were removed. Sucrose-fed rats of both strains showed large and significant increases in the rates of glucose, α-methylglucose, fructose and sucrose transport. The transport of galactose, maltose and lactose did not show consistent increases due to sucrose feeding. Although the magnitude of the increases in sugar transport due to sucrose feeding was only slightly greater in BHE than in Wistar rats, the former tended to exhibit a greater rate of sugar transport when fed either diet. Increases in serum insulin levels were observed in the sucrose-fed rats of both strains and in BHE controls. Lipogenic enzyme activity was greatly increased as a result of sucrose feeding. BHE rats, however, did not show greater levels of enzyme activity than Wistar rats. Liver lipids were increased in both the Wistar and the BHE sucrose-fed rats and in BHE rats fed the stock diet. These data diminish the possibility of a nonspecific transport effect due to differences in the availability of nutrients from either the stock or the sucrose diets.

6651 TRANSMUCOSAL TRIGLYCERIDE TRANSPORT RATES IN PROXIMAL AND DISTAL RAT INTESTINE IN VIVO. *(E.)* Wu, A.; Clark, S. B.; Holt, P. R. (Saint Luke's Hosp. Center, New York, N.Y. 10025). *J. Lipid Res.* 16(4):251-257, 1975.

Direct measurements of fractional triglyceride output rates in proximal and distal intestine, using direct regional perfusion under conditions where uptake from the lumen was complete, were utilized to test a mathematical model of lipid uptake rates. Male Wistar rats received four cannulas: abdominal thoracic duct for lymph collection; bile and pancreatic juice diversion; and two intraintestinal infusion cannulas inserted into either the duodenum (proximal) or the intestinal midpoint (distal). Infusion of donor bile and pancreatic juice (0.75 ml/hr) was begun immediately after surgery and was continued without interruption. A continuous infusion of glucose-KCl-NaCl was also administered (2.293 ml/hr for 24 hr, then 1.146 ml/hr), except during lipid infusion. Infusions of [^{14}C]triolein (1.146 ml/hr) were made for 6 hr, 48 and 72 hr after surgery. The total recovery of [^{14}C]triolein in both proximal and distal groups was more than 90% on both days. The proximal output rate reached a steady state at 3 hr after the start of infusion and plateaued at 98% of the infusion rate. Output from the distal intestinal wall was much slower initially and leveled off at 85% after 5 hr of infusion. Absorption from the lumen approached 100% in both proximal and distal intestine when measured at 3 and 6 hr. The mean half-life for the distal intestine was about 35% greater than that for the proximal intestine. The total ^{14}C-labeled lipid accumulated in the intestinal wall at the end of the 6-hr infusion period was greater in distally infused animals (22.3% of the total infused lipid compared to 13.9% in proximal intestine). Thin-layer chromatography of the tissue [^{14}C]lipid showed more than 90% of the label was in triglyceride in both proximal and distal intestine. The fractional turnover rate of the labeled lipid through the intestinal wall *in vivo* was about 40% slower in distal compared with proximal halves of rat intestine. These data support previous findings suggesting that slower distal transmucosal lipid transport is responsible for the higher tissue lipid accumulation in distal compared with proximal intestine when uptake rates are maximal.

6652 BILE CONSTITUENTS IN BLOOD AND LYMPH DURING BILIARY OBSTRUCTION. I. THE DYNAMICS OF ABSORPTION AND TRANSPORT OF IONS AND COLLOID MOLECULES. *(E.)* Szabo, G.; Magyar, Z.; Jakab, F. (Pharmacological Res. Inst., H-1430 Budapest, Hungary). *Lymphology* 8(2):29-36, 1975.

An analysis of the transport of bile constituents was made by the introduction of known amounts of Na^{125}I and ^{131}I-albumin into the biliary tract at a constant rate. The iodide ion (5 μCi) and labeled albumin (5 μCi) were infused into mongrel dogs *via* the common bile duct at pressures of 20 to 25 and 40 mm Hg, at rates of 0.1 to 0.3 or 1.1 ml/min. One group of dogs also received a single i.v. injection of the iodide ion (5 μCi). At 40 mm Hg, the amounts of the iodide ion and the labeled albumin were 73% and 68%, resp. At 25 mm Hg, the difference between ion transport and colloid molecule transport increased: values were 80% for the iodide ion and 52.5% for the labeled albumin. At 40 mm Hg, the lymphatic concentration of labeled albumin reached 36% of its concentration in the infusion fluid. It is concluded that at increased pressure fluid leaks first from the biliary ducts into the Mall's spaces. Due to water absorption and ion and small molecule diffusion into the capillaries, the concentrations of proteins or protein-bound molecules in this part of the hepatic interstitial fluid increases, reflected in their high concentration in the lymph. If bile pressure rises further, fluid also leaks into the spaces of Disse, leading to a bulk flow of solvent and solutes into the sinusoids and to the near disappearance of differences in the venous transport of ions and colloids.

6653 BILE CONSTITUENTS IN BLOOD AND LYMPH DURING BILIARY OBSTRUCTION. II. THE ABSORPTION AND TRANSPORT OF BILE ACIDS AND BILIRUBIN. *(E.)* Szabo, G.; Magyar, Z.; Szentirmai, A.; Jakab, F.; Mihaly, K. (Pharmacological Res. Inst., H-1430, Budapest, Hungary). *Lymphology* 8(2):36-42, 1975.

An attempt was made to calculate the absolute amounts of bile acids transported by the lymphatic and venous routes. Total bilirubin and bile acid concentrations were made in mongrel dogs who had received a cannula in the thoracic duct, as well as cystic and common bile duct ligation. Lymph samples were collected for 8 hr in 2-hr periods, and subsequently up to 24 hr in two 8-hr periods. Lymphatic concentrations of both bilirubin and bile acids attained maximum levels between the fourth and sixth hr (4.82 mg% for bilirubin, while the normal value was 0.20 mg%; 116 μM/l for bile acids, while the normal value was 1 μM/l). Lymphatic concentrations remained above plasma concentrations during the whole 24 hr. The amounts of both substances transported by the lymph system rose steadily for 6 and 8 hr, resp., and after 2 hr of occlusion they exceeded the amounts transported by the venous system. From these data it is suggested that in the first hr after biliary occlusion, the concentration of bilirubin and especially that of bile acid in the interstitial fluid of the liver is near the maximal binding capacity of the proteins present in the same fluid.

6654 DIABETES MELLITUS: CHANGES IN THE TRANSPORT PROPERTIES OF ISOLATED INTESTINAL MICROVILLOUS MEMBRANES. *(E.)* Hopfer, U. (Dept. Biochemistry, Federal Inst. Technology, Zurich, Switzerland). *Proc. Nat. Acad. Sci. USA* 72(6):2027-2031, 1975.

The transport properties of the luminal plasma membranes of small intestinal epithelial cells from normal and diabetic rats were compared. Jejunal and ileal mucosal samples were isolated from rats killed 4-8 days after injection with alloxan (50 mg/kg) or saline solution (control). Accumulation of D-glucose was greater in diabetic membrane segments with the addition of NaCl or NaSCN (1.5 and 2.0, resp., measured as the ratio of maximum over equilibrium uptake of D-glucose) compared with controls (1.1 and 1.4, resp.). Increasing the glucose-independent Na$^+$-conductance of the membrane with monactin (50% ethanolic solution) or gramicidin D reduced the active accumulation of D-glucose by membrane preparations from both control and diabetic rats. Concentrations of both ionophorous antibiotics in the incubation medium of diabetic membrane vesicles could be adjusted so that D-glucose transport was indistinguishable from control membranes not treated with ionophores. It is suggested that the microvillous membranes are a site for the changes which occur in diabetes mellitus. It is further suggested that the change in transport properties of the isolated membranes may explain the simultaneous elevation of active intestinal sugar, amino acid and bile salt transport in intact intestinal tissue.

6655 JEJUNAL AND ILEAL ABSORPTION OF DIBASIC AMINO ACIDS AND AN ARGININE-CONTAINING DIPEPTIDE IN CYSTINURIA. *(E.)* Silk, D. B. A.; Perrett, D.; Clark, M. L. (Saint Bartholomew's Hosp., London, England). *Gastroenterology* 68(6):1426-1432, 1975.

Jejunal perfusion studies with an arginine-containing dipeptide, L-arginyl-L-leucine, were performed in cystinuric patients and normal controls to evaluate the role of the specific dibasic amino acid transport system. Amino acid absorption from the jejunum and ileum of six male homozygous cystinuric patients was assessed and the results were compared with those obtained in sex- and age-matched controls. Solutions containing either glycine (4.2 mM) plus lysine (4.2 mM) or arginine (1 mM) plus leucine (1 mM) were perfused. Jejunal absorption of L-arginyl-L-leucine was also investigated by perfusion of 1 mM in the jejunum of patients and controls. Both jejunal and ileal absorption of glycine and L-leucine were normal in patients compared to controls, but there was severe impairment ($p < 0.001$) during jejunal and ileal perfusion with L-lysine and L-arginine. The rates of uptake of both L-arginine and L-leucine were similar in both patients and controls during perfusion with the dipeptide. Higher concentrations of L-arginine were detected during perfusion with the dipeptide in cystinuria patients (26.7 μM/100 ml) compared with controls (7.6 μM/100 ml). These data suggest a defect of specific carrier-mediated transport of the dibasic amino acids throughout the whole of the small intestine in patients with cystinuria. It is concluded that specific amino acid transport systems may play an important role during intestinal transport of peptides.

6656 REGIONAL DIFFERENCES IN OXALATE ABSORPTION BY RAT INTESTINE: EVIDENCE FOR EXCESSIVE ABSORPTION BY THE COLON IN STEATORRHEA. *(E.)* Saunders, D. R.; Sillery, J.; McDonald, G. B. (Dep. Medicine, RG-20, Univ. Washington, Seattle 98195). *Gut* 16(7):543-548, 1975.

To elucidate the pathogenesis of enteric hyperoxaluria, the effects of bile salts, calcium, and long-chain fatty acid on the absorption of oxalate and water by the rat intestine were studied *in vivo* using fasted male Sprague-Dawley rats. The animals were anesthetized and jejunal, ileal, and colonic sections were created. The jejunal segments were in the proximal 50 cm of the small intestine; the ileal segments extended orad from a point 5 cm from the ileocecal junction, and the colonic segments were distal to the cecum. Absorption was measured under steady-state conditions during single pass infusions, each intestinal segment serving as its own control. In the jejunum, taurocholate (10 mM), the principle salt in rat bile, depressed the absorption of both oxalate and water. Absorption was not depressed further by Ca^{++} (1 mM) or linoleic acid (2 mM). In the ileum, taurocholate did not inhibit absorption, but linoleic acid depressed the absorption of both oxalate and water. In the colon, taurocholate decreased the absorption of both substances; linoleic acid further depressed the net water transport, but it enhanced the absorption of oxalate. Calcium negated the inhibitory effect of linoleic acid on water transport and the stimulative effect of linoleic acid on oxalate absorption. When a lower concentration of taurocholate (2.5 mM) was infused into the colon, net water transport and oxalate absorption were unaffected by calcium or linoleic acid with calcium. Linoleic acid without calcium depressed net water transport but did not inhibit oxalate absorption. It is concluded that long-chain fatty acids may enhance the absorption of oxalate from the rat colon, an observation which may be relevant to understanding the process of hyperoxaluria in patients with steatorrhea.

6657 EFFECT OF CHANGES IN FEEDING SCHEDULE ON THE DIURNAL RHYTHMS AND DAILY ACTIVITY LEVELS OF INTESTINAL BRUSH BORDER ENZYMES AND TRANSPORT SYSTEMS. *(E.)* Stevenson, N. R.; Ferrigni, F.; Parnicky, K.; Day, S.; Fierstein, J. S. (Rutgers Medical Sch., Piscataway, N.J. 08854). *Biochim Biophys. Acta* 406(1):131-145, 1975.

The diurnal rhythms and daily activity levels of the intestinal glucose-galactose transport, lactase, maltase, sucrase, trehalase, γ-glutamyltransferase, alkaline phosphatase, and leucylnaphthylamide-hydrolyzing systems were studied in male Sprague-Dawley rats maintained on *ad libitum* and restricted (to the period from 2:00 to 4:00 pm daily) feeding regimens. Lighting was constant during the experimental period. The animals were killed at specific times during the seventh day of the study. The protein content of the intestinal mucosal homogenates showed no diurnal rhythmicity and did not vary according to feeding regimen. The various enzymes and transport systems tended to show higher activities at various times between 12:00 P.M. and 12:00 A.M. in the *ad libitum* group, while lower activities occurred at various times between 11:00 A.M. and 9:00 P.M. Leucylnaphthylamide-hydrolyzing activity was reduced until 12:00 A.M. and lactase activity was reduced until 3:00 A.M. In general, there was a 12-hr shift in the activity patterns between the *ad libitum* group and the restricted group. In the latter, higher activity was observed between 12:00 A.M. and 9:00 P.M. for all systems except alkaline phosphatase, which was highest from 6:00 P.M. to 3:00 A.M. Lower activity occurred between 12:00 A.M. and 2:00 P.M. for all systems except the leucylnaphthylamide-hydrolyzing system, which was lower from 3:00 A.M. to 9:00 P.M., and alkaline phosphatase, which was lower from 5:00 A.M. to 5:00 P.M. In comparison with the *ad libitum* group, the restricted group showed decreased leucylnaphthylamide-hydrolyzing activity, similar alkaline phosphatase activity, and increased activities in all other systems. Thus, at certain times of the day, the enzyme and transport system activities were similar in the *ad libitum* and restricted groups, while at other times the activities differed by as much as 341%. The data indicate that correlations between diet and intestinal enzyme or transport activity level can be made with confidence only after both the entire diurnal rhythmicity pattern and the mean daily activity levels have been determined.

MOTILITY

6673 LONGITUDINAL CONTRACTIONS IN THE DUODENUM: THEIR FLUID-MECHANICAL FUNCTION.

(E.) Melville, J.; Macagno, E.; Christensen, J. (Iowa Inst. Hydraulic Res., Iowa City, Iowa 52242). *Am. J. Physiol.* 228(6):1887-1892, 1975.

The hypothesis that contractions of the longitudinal muscle layer occur in the duodenum independently of those of the circular muscle layer and that these contractions induce the flow of the duodenal contents was investigated. Segments of duodenum were removed from healthy adult opossums of both sexes and immersed in a bath of Krebs solution with the ends tied to horizontal glass tubes. The segments were photographed during periods of longitudinal muscle contraction when the circular muscle layer appeared inactive. Relative displacements as a function of time were determined based on the movement of India ink spots on the serosal surface. The frequency and velocity of the duodenal slow waves were also recorded under normal illumination and during exposure to high-intensity photography lamps. The frequency of longitudinal oscillation of the marked points on the duodenal segments was 20.5 cycles/min, the longitudinal displacement wave spreading caudad with an average velocity of 3.27 cm/sec. The slow wave frequency in the segments was 17.9 cycles/min with a propagation velocity of 1.63 cm/sec under normal illumination. Under the high-intensity lamps, the frequency increased to 18.9 cycles/min. In a 2-dimensional mechanical model, flow induced by simulated longitudinal contractions was visualized and a theoretical model of axisymmetric flow was made. Based on this model, it is concluded that independent contractions of the longitudinal muscle layer appear driven by the electrical slow waves of the duodenum and that they are capable of inducing a pattern of flow in which the duodenal contents flowed between the core and the periphery of the intestinal conduit.

6674 ULTRADIAN RHYTHMS IN WAKING GASTRIC ACTIVITY.

(E.) Hiatt, J. F.; Kripke, D. F. (Narcotic Treatment Program, 1300 Market St., San Diego, Calif. 92101). *Psychosom. Med.* 37(4):320-325, 1975.

Ultradian rhythms in waking gastric activity were studied in six female and five male young adult volunteers. The subjects were fasted and nasogastric tubes with rubber balloons on the end were inserted to monitor gastric contractions. The electroencephalogram (EEG), electrooculogram (EOG), and electromyogram (EMG) were monitored by a multiplex telemetry transmitter worn in a special cap. The intraluminal gastric pressure records over the 8-hr experimental session showed a tendency for periods of intense gastric contraction to recur at regular intervals. The typical subject showed 4 to 5 cycles in the 8-hr period. The intense contraction periods within these cycles lasted about 18 min and were characterized by an increase in the peak pressure of individual contractions and increases in baseline pressure between contractions. The contraction periods were preceded by gradually increasing activity followed by an abrupt decrease. Although the modal duration of a cycle was 100 min, the cycle was about 200 min in three subjects. There was a tendency for those subjects with elevated scores on the Minnesota Multiphasic Personality Inventory to show poor or absent (12 to 18 cycles/day) rhythms in the gastric recordings. The degree of rhythmicity was inversely correlated with paranoia scores and positively correlated with scores on the Goldberg Scale, which distinguishes psychotic from neurotic processes. The ultradian cycle observed in the waking subjects bore a striking resemblance to previously recorded sleep cycle patterns. The data combined with previous data suggest that both appetitive and consummatory aspects of alimentary function may display ultradian rhythms.

6675 THE INTRINSIC INNERVATION OF THE HUMAN ALIMENTARY TRACT AND ITS RELATION TO FUNCTI

(E.) Bennett, A.; Stockley, L. (King's Coll. Hosp. Medical Sch., London, England). *Gut* 16(6):443-453, 1975.

The intrinsic innervation of the human gut was studied in strips of circular and longitudinal muscle removed form various regions of the alimentary canal at operation. The strips, all free of the effects of drugs used at surgery, were electrically stimulated (0.1-12 Hz) with square-wave pulses of alternating polarity generated by linked stimulators. Specimens of lower esophageal smooth muscle were obtained from eight patients; 14 circularly cut strips varied in response, generally contracting at 0.1-0.5 Hz, while 10 longitudunal muscle strips were predominantly contracted by electrical stimulation, optimally at 4 Hz. In 52 specimens of gastric body and antrum, electrical stimulation usually elicited contractions which increased as the frequency was raised. Specimens of terminal ileum proximal to the ileocaecal spincter (15 patients) showed circular muscle contracted at 0.1-0.5 Hz, and longitudinal contractile responses at 1-64 Hz. The responses of nine specimens of ascending colon were similar to those reported for the sigmoid colon. Variations, most pronounced at 4 Hz, illustrated a clear gradient of response from the stomach to colon in the longitudinal muscle, with excitation dominant proximally and inhibition dominant distally. The neuronal nature of the response to electrical stimulation was tested with tetrodoxin plus a variety of other drugs, including hexamethonium bromide, KCl, $BaCl_2$, acetylcholine perchlorate, atropine, and hyoscine. The esophageal responses showed that both layers receive excitatory and inhibitory innervation, with cholinergic excitation generally predominating in the distal longitudinal layer. In the stomach, cholinergic contractions converted to nonadrenergic relaxations in the presence of hyoscine. The unresponsiveness of the gastric body circular muscle was attributed to its insulated anatomy. Types of responses in the ileum suggested both adrenergic and nonadrenergic inhibitory nerves, dependent on the type of stimulation. Although gut motility may also be affected by locally released substances or circulating hormones, it is suggested that electrical slow wave activity and the intrinsic innervation are fundamental for the control of normal gut activity. Both revealed gradients down the gut relating to regional differences in function.

6676 THE VAGUS, THE DUODENAL BRAKE, AND GASTRIC EMPTYING.

(E.) Shahidullah, M.; Kennedy, T. L.; Parks, T. G. (Dep. Surg., Queen's Univ., Belfast, Northern Ireland). *Gut* 16(5):331-336, 1975.

The site of duodenal receptors regulating gastric emptying rates was investigated, and the role of the vagus in the regulation of gastric emptying with an intact pylorus was also studied. Gastric emptying studies were carried out before and after vagotomy on two groups of dogs with gastric and duodenal fistulas produced by inserting Gregory cannulas into the stomach and duodenum, resp. The gastroduodenal junction was left intact in the first group, but in the second the pylorus was implanted end-to-side 50 cm further down the small intestine. Five dogs in the first group underwent truncal vagotomy and two dogs in the second group underwent extragastric selective vagotomy. In emptying studies performed 6 to 10 weeks after preparation of fistulas, 600 ml of fluids were used in seven dogs with an intact gastroduodenal junction. The rate of emptying of different instillates varied greatly, with mean emptying times of: deionized water, 44 min; hydrochloric acid, 85 min; dextrose, 126 min; and fat, 144 min. After truncal vagotomy the emptying time for each instillate became significantly longer, but the proportional differences were maintained. In eight dogs with the pylorus implanted into the small intestine, emptying studies utilized 500 ml of different substances introduced into the stomach with 100 ml of deionized water through the duodenal cannula. With water in the duodenum, different instillates emptied from the stomach at similar rates. In four of these dogs, 500 ml of water was instilled into the stomach and 100 ml of different instillates were introduced into the duodenum, resulting in the following mean emptying times: water, 54 min; 250 mM HCl, 80 min; 10% dextrose, 137 min; and 5% fat, 160 min. In two dogs after extragastric selective vagotomy, the rate of emptying of water, dextrose, and fat were similar. These studies indicate that most, if not all, the duodenal braking receptors lie in the proximal 50 cm of the small intestine. It is concluded that vagal innervation of the stomach in dogs is important in gastric emptying, but duodenal innervation is not essential for the function of the braking receptors which appear to work through a hormonal mechanism.

6677 CONTROL OF THE INTERDIGESTIVE MYOELECTRIC ACTIVITY IN DOGS BY THE VAGUS NERVES AND PENTAGASTRIN.

(E.) Marik, F.; Code, C. F. (Mayo Clinic, Rochester, Minn.). *Gastroenterology* 69(2): 387-395, 1975.

The effects of vagotomy and pentagastrin on the interdigestive complex were studied in eight healthy, conscious, fasted female mongrel dogs. The electrical activity of the stomach and small intestine were recorded using surgically implanted monopolar electrodes, and the normal characteristics of the interdigestive myoelectric complex were determined in each dog. The electrical activity of the complex was then recorded during the i.v. infusion of pentagastrin (0.1 μg/kg/min for 10-150 min beginning at various phases during the cycle of the complex), after vagotomy, and during pentagastrin infusion after vagotomy. In intact dogs, pentagastrin infusion interrupted that interdigestive myoelectric complex in the stomach and small intestine and replaced it with activity which closely resembled that seen after feeding. After bilateral transthoracic vagotomy, pentagastrin still interrupted the complex. However, a premature activity front (phase III) of the complex was initiated in the stomach and duodenum after the cessation of pentagastrin infusion; this activity migrated in a normal fashion distally along the small bowel. Vagotomy was also followed by a reduction in the temporal regularity of the cycles of the complex. Fewer cycles/10 hr occurred in most dogs after vagotomy than before surgery, and the complexes were not as regularly interrupted by feeding a small meal (50 g meat) as they had been before vagotomy. The results indicate that both neural and hormonal influences have a role in controlling the interdigestive motor complex in dogs.

6678 INFLUENCES ON COLONIC AND SMALL INTESTINAL MOTILITY BY THE CEREBELLAR FASTIGIAL NUCLEUS.

(E.) Martner, J. (Dept. Physiology, Univ. Goteborg, Sweden). *Acta Physiol. Scand.* 94(1):82-94, 1975.

The fastigial influence on intestinal motility was investigated in acute experiments on chloralosed cats of both sexes. In most animals, the adrenals were ligated and i.v. hydrocortisone (10 mg/kg) was given. Arterial pressure was recorded through a femoral catheter and intestinal motility was recorded in isolated small intestinal and colonic segments, those portions of the small intestine not being used for recording being extirpated, along with the spleen and greater omentum. The vagal and pelvic nerves were dissected and placed on ligatures. Intestinointestinal inhibitory reflexes were elicited by graded distention of a small isolated intestinal loop or by afferent stimulation of thin mesenteric pedicles. For baroreceptor stimulation, one carotid sinus region was isolated and perfused with femoral artery blood and topical cerebellar stimulations were induced by the Horsley-Clarke technique. After each experiment, the cerebellum and adjacent brainstem structures were examined histologically. Electrical stimulation of the rostral fastigial pole produced a rise in blood pressure, increased motor activity in the ileum and colon, and increased and decreased motility responses in the jejunum. The intestinal responses were neither secondary to changes in intestinal blood flow nor to baroreceptor reflexes induced by the increased blood pressure. The excitatory responses were not due to increased parasympathetic activity since sectioning of such pathways failed to abolish the responses. Interruption of adrenergic sympathetic discharge did, however, eliminate these responses, indicating that the fastigial effects were mediated by the suppression of the prevailing adrenergic tone. Noxious stimuli to the abdomen, including laparotomy, inhibited intestinal motility by a reflex increase in adrenergic discharge. It is suggested that the fastigial influence on intestinal motility is due primarily to suppression of this reflex.

6679 INFLUENCES ON THE DEFECATION AND MICTURITION REFLEXES BY THE CEREBELLAR FASTIGIAL NUCLEUS. *(E.)* Martner, J. (Dept. Physiology, Univ. Goteborg, Sweden). *Acta Physiol. Scand.* 94(1):95-104, 1975.

The influence of the cerebellar fastigial nucleus on the defecation and micturition reflexes was studied in chloralosed cats. The Horsely-Clarke technique was used for cerebellar stimulation and the defecation reflex was elicited by afferent stimulation of one cut pelvic nerve or by application of mechanical friction to the rectal mucosa. The small intestine, spleen, and greater omentum were extirpated and in most animals the adrenals were ligated, adrenocortical substitution being given by i.v. hydrocortisone. Catheters were used to record arterial pressure and bladder and colonic motilities were recorded from an isolated perfused proximal colonic loop. Gallamine iodide, guanethidine, bidenzyline, phentolamine, propranolol, and/or atropine were given i.v. in some experiments. Whenever effective, topical fastigial stimulation regularly suppressed both the somatomotor and autonomic components of the defecation reflex; the straining movements and the colonic vasodilatator and motor responses associated with defecation were completely inhibited. Bladder motility could be either suppressed or enhanced, depending on the prevailing bladder tone and on the fastigial site stimulated. The autonomically conveyed inhibitory responses were in both cases independent of the adrenergic sympathetic pathways, since both were unaffected by sympathetic nerve sectioning and by adrenergic blocking drugs, but were eliminated by pelvic nerve section. It is suggested that these fastigial inhibitory influences are exerted on the spinal parasympathetic reflexes controlling both bladder and colon. The rostral ventromedial fastigial pole appears to be involved in sympathetic and parasympathetic autonomic mechanisms, affecting both bladder responses and the defecation reflex.

6680 THE MUCOSAL LINING OF THE INTRAMURAL COMMON BILE DUCT AS A DETERMINANT OF DUCTAL OPENING PRESSURE. *(E.)* Tansy, M. F.; Salkin, L.; Innes, D. L.; Martin, J. S.; Kendall, F. M.; Litwack, D. (Temple Univ. Health Sciences Center, 3223 North Broad St., Philadelphia, Pa. 19140). *Dig. Dis.* 20(7):613-625, 1975.

Histological evidence was sought for the presence of ductal mucosal folds in the intramural portion of the common bile duct of the pigeon, rabbit, cat, dog and human. Common bile duct samples from all species were specifically stained with hematoxylin and eosin and examined microscopically. In other experiments, norepinephrine, histamine, and bethanechol were administered intraductally or i.v. to cats and dogs and the effects on the systemic arterial blood pressure and opening pressures of the choledochoduodenal junction were studied. Structural studies in dogs were also undertaken to compare the luminal topographies of the intramural and extramural portions of the common bile duct. The lumen of the intraduodenal portion of the common bile duct was almost completely filled by folds of a highly vascularized mucosa in all five species studied. These folds were most apparent near the intraduodenal ductal orifice, where they almost completely occluded the lumen. Histological studies in dogs indicated that the mucosal topographies of the extramural and intramural portions of the duct were markedly different. The physiological data in dogs and cats indicate that changes in the systemic arterial blood pressure were associated with changes in the opening pressures of the choledochoduodenal junction; these changes varied in the same direction. The bile duct opening pressures in these two species were increased by the intraductal administration of histamine and were reduced by intraductal norepinephrine. When given i.v., the effects of these drugs were the opposite of those produced by intraductal treatment; however, the secondary effects after i.v. treatment were the same as the effects after intraductal treatment. Histological examination of the intraductal folds subsequent to intraductal histamine revealed a marked vascular engorgement. It is concluded that the most significant determinant of changes in the ductal opening pressures in the cat and dog is probably the state of the mucosal vasculature within the terminal portion of the common bile duct.

6681 INTRALUMINAL AND INTRAPERITONEAL PRESSURES AT THE CARDIA: EFFECT OF HORMONES AND SURGICAL INTERVENTION. *(E.)* Moossa, A. R.; Cooley, G. R.; Skinner, D. B. (Univ. Chicago Hosp. Clinics, Ill.). *Surg. Forum* 24:370-372, 1974.

The effects of hormonal administration, fundic excision, and esophagogastrectomy on the intraluminal and extraluminal pressures in the cardia were studied in Rhesus monkeys. Six refluxing and six nonrefluxing monkeys were given pentagastrin, secretin, and cholecystokinin (CCK-PZ) at varying rates by i.v. infusion or s.c. injection; the intraluminal and extraluminal pressures were monitored by surgically placed catheters. The refluxers were those whose esophageal pH at 3 cm above the intraluminal high-pressure zone at the cardia fell to below 4 at any time during a 5-day study. Fundic excision was performed on two nonrefluxers and esophagogastrectomy was performed on three more nonrefluxers; the effects of the gastrointestinal hormones were also assessed in the latter animals. The extraluminal pressures at the cardia correlated much better with gastroesophageal reflux than did the intraluminal pressures. The gastrointestinal hormones had a variable effect on the intraluminal pressures but did not influence the extraluminal pressures or reflux. It is concluded that external factors other than the angle of His are more important in preventing reflux than any true sphincter under hormonal control.

6682 THE EFFECTS OF PREMEDICATION DRUGS ON THE LOWER OESOPHAGEAL HIGH PRESSURE ZONE AND REFLUX STATUS OF RHESUS MONKEYS AND MAN. *(E.)* Hall, A. W.; Moossa, A. R.; Clark, J.; Cooley, G. R.; Skinner, D. B. (Pritzker Sch. Med., Univ. Chicago, Ill.). *Gut* 16(5):347-352, 1975.

The effects of morphine sulfate (7-10 mg for humans; 1 mg for monkeys), pethidine hydrochloride (40-50 mg, humans; 5-7 mg, monkeys), and diazepam (2.5-10 mg, humans; 0.5-1 mg, monkeys) on the high pressure zone and the reflux status of Rhesus monkeys and man were studied. Esophageal motility was studied by standard manometry in 35 fasting human volunteers and in eight fasting monkeys. The high pressure zone in man was measured as the difference between the end expiratory intragastric pressure and the mean peak pressure in the lower esophagus. In monkeys, the mean intragastric value was subtracted from the mean of the peak lower esophageal pressure. Gastrointestinal reflux was measured using a Beckman intestinal pH electrode which was passed *via* the nostril until it lay in the lower esophagus. The high pressure zone pressure decreased significantly in man after morphine (42.3%) and pethidine (51.61%), and almost significantly after diazepam (35.42%). The reductions in high pressure zone pressures were significant in monkeys after all three drugs (46.3, 52.4, and 59.2% for morphine, pethidine, and diazepam, resp.). Significant reflux, as measured by a score greater than 2 of 20 (reflux in all positions tested), was seen in 14 humans, and injection of drugs increased the numerical reflux score by a mean of 6.35. Drug injection caused reflux (mean, 9.7) in 13 (59%) of 22 subjects who did not reflux on control testing. In monkeys, the relation between the high pressure zone and reflux status depended on the numerical value of the high pressure zone pressure. It is concluded that great caution must be exercised in the administration of these drugs in doses sufficient to cause drowsiness in subjects who will not be under constant skilled supervision, due to the increased risk of regurgitation and pulmonary aspiration.

6683 EFFECT OF NICOTINE ON THE LOWER ESOPHAGEAL SPHINCTER. STUDIES ON THE MECHANISM OF ACTION. *(E.)* Rattan, S.; Goyal, R. K. (Univ. Texas Health Science Center, Dallas, Tex.). *Gastroenterology* 69(1):154-159, 1975.

The effect of nicotine on the lower esophageal sphincter (LES) pressure in anesthetized opossums and the site of its action were studied. Opossums (*Didelphis virginiana*) were anesthetized, and intraluminal pressures were measured with a water-filled and continuously-perfused catheter system. Drugs were administered i.v.: nicotine sulfate (5-4000 μg/kg), atropine sulfate (30 μg/kg), propanolol (1 mg/kg), reserpine (3 mg/kg, twice) and hexamethonium. Nicotine sulfate caused a dose-dependent reduction in LES pressure. The threshold dose was less than 5 g/kg. The dose of 50 g/kg produced the maximal reduction in pressure (85%). Bilateral cervical vagotomy did not alter the effects of nicotine, nor did the adrenergic antagonist propanolol, or reserpine. Neither atropine nor hexamethonium (20 mg/kg) altered the effects of nicotine. LES response to 50 g/kg of nicotine during slow i.v. administration of 4 mg/kg of nicotine was markedly attenuated, indicating tachyphylaxis. The LES pressure during nicotine tachyphylaxis was 28.1 mm of Hg, and was reduced to only 23.9 mm of Hg with 50 g/kg of nicotine. The initial LES pressure fell 86.9% in five animals with a small dose of 0.2 g/kg of nicotine in the branch of the left gastric artery supplying the lower esophageal sphincter. There was a significant difference observed after electrical stimulation of the peripheral end of the vagus after bilateral cervical vagotomy between control (83.3%) and tachyphylaxis (31.8%). These data indicate a dose-dependent reduction in LES pressure following nicotine administration.

6684 FORCE VELOCITY CHARACTERISTICS OF OESOPHAGEAL MUSCLE: INTERACTION OF ISOPROTERENOL AND CALCIUM. *(E.)* Cohen, S. (Univ. Pennsylvania Hosp., 3400 Spruce St., Philadelphia, Pa. 19104). *Eur. J. Clin. Invest.* 5(3):259-265, 1975.

The interaction of isoproterenol and calcium on the force velocity characteristics of esophageal smooth muscle were evaluated. Smooth muscle strips were obtained from 20 adult opossums, and mounted to record tension generated by the circular layer. To obtain the force-velocity relation, the neurogenic response elicited at the termination of electrical stimulation was utilized. Force-velocity curves were constructed during superfusion of Kreb's solution containing 5.0 mM Ca^{++} as well as the usual 2.5 mM Ca^{++}. After determination at the different calcium concentrations, isoproterenol (10^{-7}, 10^{-6}, 10^{-5}, and 10^{-4} M) was added to the superfusate. All muscle was studied at its length of optimal tension development (Lo). The maximal velocity of shortening (V_{max}) and the peak force (Po) of esophageal muscle were 6.2 mm/sec and 16.8 g, resp., at 2.5 mM calcium. Isoproterenol (10^{-5} M) decreased the V_{max} to 4.9 mm/sec and the Po to 9.8 g ($P < 0.01$). Increased calcium (5.0 mM) alone did not alter either V_{max} or Po. At 5.0 mM calcium, 10^{-5} isoproterenol reduced the V_{max} to 6.0 mm/sec and the Po to 13.9 g. These studies indicate that isoproterenol significantly reduces the V_{max} and Po of esophageal smooth muscle during the neural mediated 'off response.' This effect of isoproterenol is reversed in part by an increase in calcium concentration.

6685 EFFECTS OF TEMPERATURE AND INORGANIC IONS ON CALCIUM ACCUMULATION IN MICROSOMES FROM INTESTINAL SMOOTH MUSCLE. *(Eng.)* Hurwitz, L.; Debbas, G.; Little, S. (Univ. New Mexico Sch. Medicine, Albuquerque, N. M.). *Mol. Cell. Biochem.* 8(1): 31-42, 1975.

The effects of alterations in temperature and in the inorganic ion composition of the bathing medium on the mechanical activity in intact muscle fibers and ATP-dependent calcium accumulation in microsomal vesicles were studied using the isolated longitudinal smooth muscle from guinea pig small intestine. The temperature was maintained at 10 or 30° C and the bathing medium contained $CdCl_2$, $BaCl_2$ and/or $MnCl_2$. Isotonic contractions of the longitudinal muscle were recorded following the addition of acetylcholine bromide (1.4×10^{-6} M) to the medium, and a microsomal fraction of muscle was assayed for calcium uptake and release and examined by electron microscopy. A reduction in temperature from 30 to 10 C inhibited the microsomal uptake and release of calcium. The change in temperature also slowed the rate of relaxation of the intact muscle after acetylcholine-induced contraction. The presence of $CdCl_2$ in the medium also decreased the uptake of calcium into the microsomal vesicles, but the release of calcium from the microsomes was accelerated. $BaCl_2$ had similar but less marked effects on calcium uptake and very little effect on calcium release. $MnCl_2$ had no significant effects on either uptake or release. Whereas both $CdCl_2$ and $MnCl_2$ exerted an inhibitory influence on the acetylcholine-induced contractile responses of the intact muscle fibers, $BaCl_2$ served to initiate a contractile response. Thus, the effects of temperature on microsomal calcium binding can be correlated with the effects on mechanical activity in the intact fibers, but the effects of $CdCl_2$, $BaCl_2$, and $MnCl_2$ on these two cellular processes do not show any consistent pattern.

6686 SUBSTITUTION OF Ca^{++} WITH Ba^{++} AND Mn^{++} ON THE TONIC AND PHASIC CONTRACTIONS OF THE SMOOTH MUSCLE OF THE STOMACH. *(E.)* Boev, K.; Papazova, M.; Milousheva, E. (Bulgarian Acad. Sci.). *C. R. Acad. Bulg. Sci.* 28(4):553-556, 1975.

The effects of replacing Ca^{++} in the bathing solution with Ba^{++} or Mn^{++} on the tonic and phasic contractions of the feline gastric smooth muscle was studied *in vitro*. Isolated strips of stomach were bathed in Krebs solution; in some experiments, sucrose (137 mN), $BaCl_2$ or $MnCl_2$ (10^{-4} M), acetylocholine (10^{-8}, 10^{-7}, or 10^{-6} M), D_{609} (10^{-5} M), nitroprusside sodium (10^{-5} or 10^{-6} M), and/or EDTA (5.10^{-4} M) were added to the solution. The sucrose gap method was used to study the electric and contractile activities of the muscle preparations. The phasic contractions of the antral muscle strips were completely inhibited by EDTA treatment and the removal of Ca^{++} from the nutrient medium; the spontaneous myogenic tonus of the fundic strips was also abolished under these conditions. The addition of $BaCl_2$ to the Ca^{++}-deprived or EDTA-treated media led to a gradual restoration of the phasic activities in these strips. D_{609}, but not sodium nitroprusside, completely blocked the Ba^{++}-induced phasic contractions. The contractile activity in the strips bathed in medium containing EDTA but no Ca^{++} disappeared prior to the appearance of characteristic changes in the bioelectric activity of the preparation. Acetylcholine activated the contractile activity of the preparations in the presence of $BaCl_2$, but had no such effect on medium containing neither Ca^{++} nor Ba^{++}. In small doses, Mn^{++} inhibited the tonic contractions of the fundic strips but had no influence on the phasic contractions of the antral strips. When added to a Ca^{++}-free medium containing EDTA, Mn^{++} caused a gradual increase in the tonic contractions of the fundic and body strips; this effect was observed in the presence of D_{600} but was blocked by sodium nitroprusside. The data indicate that the mechanisms of action of Ba^{++} and Mn^{++} on the smooth muscle cells of the stomach differ. They also emphasize the specificity which is characteristic of the different smooth muscles of the stomach.

6687 MODIFICATION BY EXTERNAL CALCIUM AND MAGNESIUM IONS OF THE POTENTIATIVE ACTION OF 5'-AMP ON THE ATP-INDUCED CONTRACTION OF ISOLATED GUINEA-PIG ILEUM. *(E.)* Iso, T. (Res. Lab., Santen Pharmaceutical Co., Ltd., Higashiyodogawa-ku, Osaka, Japan). *Jpn. J. Pharmacol.* 24(5):797-801, 1974.

Studies were undertaken to determine the effects of Ca^{++} and Mg^{++} concentrations in Tyrode solution on the contractile responses of isolated guinea-pig ileum to adenine nucleotides and acetycholine. ATP and ADP, but not AMP, produced contractions in the isolated ileum, with the contractile activity of ADP about three times as potent as that of ATP. Lowering the Mg^{++} concentration below 1.0 mM (normal) enhanced the contractile responses to ATP and acetycholine, but lowering the Ca^{++} concentration from 1.8 to 0.1 mM depressed the responses. This inhibitory effect of low Ca^{++} on the contractile responses to low ATP concentrations (3×10^{-6} to 3×10^{-5} M) was not observed in the absence of Mg^{++}; in contrast, the response to acetycholine was depressed by 0.1 mM Ca^{++} in Mg^{++}-free medium. In normal Tyrode solution, the response to ATP was significantly potentiated by 5'-AMP (1 mM) but depressed by adenosine (1 mM). The contractile response to acetylcholine was slightly depressed by both 5'-AMP and adenosine. The potentiative action of 5'-AMP on the ATP-induced contraction in normal Tyrode solution disappeared at 0.1 mM Ca^{++} in Mg^{++}-free medium. The inhibitory effects of 5'-AMP and adenosine on the acetylcholine-induced contraction were augmented by 0.1 mM Ca^{++}, as was the inhibitory effect of adenosine on the ATP-induced contraction. It is suggested that the depolarized state after low Ca^{++} may play an important role in augmenting the inhibitory effect of 5'-AMP, although the mechanism of actions remains to be elucidated.

6688 THE EFFECT OF CHOLECYSTOKININ ON ELECTRICAL SPIKE POTENTIALS AND INTRALUMINAL PRESSURE VARIATIONS IN THE HUMAN SMALL INTESTINE. *(E.)* Oigaard, A.; Dorph, S.; Christensen, K. C.; Christiansen, L. (Rigshospitalet, Blegdamsvej 9, Copenhagen, DK-2100, Denmark). *Scand. J. Gastroenterol.* 10(3): 257-262, 1975.

The effect of cholecystokinin (CCK) on duodenal motility was studied in six patients with inguinal hernia and in nine patients with cholecystolithiasis. The effect of CCK on ileal motility was studied in six patients who had been treated with ileostomy for ulcerative colitis; of the cholecystolithiasis patients, five were studied before and after cholecystectomy, two were studied only preoperatively, and two were studied only postoperatively. Probes were passed into the distal part of the descending duodenum or about 10 cm into the ileum through the ileostomy. Recordings of the electrical spike potentials and intraluminal pressure were made before and after i.v. CCK (80 dog Ivy U, given over a 2-min period). In the duodenum, quantitative calculations of motility gave identical values before and after drug administration, and the results were identical in the cholecystolithiasis patients before and after surgery and in the hernia patients. A decrease in the amplitude of the spike potentials was observed in the duodenum during the first few min after drug administration in all groups. Recordings in the distal ileum showed a significant increase in motility after CCK, with no change in the spike potential amplitude. The data suggest that CCK has no effect on duodenal activity but that it does in some way modify the electrical activity of the smooth muscle cell.

6689 ELECTRICAL SPIKING ACTIVITY AND PROPULSION IN SMALL INTESTINE IN FED AND FASTED RATS.

(E.) Ruckebusch, M.; Fioramonti, J. (Dept. Physiology, Natl. Veterinary Sch., 31076 Toulouse, France). *Gastroenterology* 68(6):1500-1508, 1975.

The role of food consumption on the pattern of the electrical spiking activities of the small intestine and on the time course of small intestinal propulsion were examined in male Wistar rats. From two to eight pairs of electrodes 2 mm apart were positioned at intervals of 10 cm; the first site was 10 cm from the pylorus. An indwelling polyethylene tube was placed in the duodenum or jejunum beneath an electrode site, and in the ileum, in 40 rats. Of these, 10 also had a gastric cannula. All rats were fed and received water *ad libitum* four days/week, and were fasted for 3 days/week. In both the fed and fasted rats, slow waves occurred at a high frequency in the duodenum (36-40/min) compared to the ileum (30/min). Almost continuous irregular spiking was recorded in fed rats, characterized by randomly occurring short spike bursts. The electrical spiking in fasted rats 6 hr after food withdrawal became regularly interspersed at 15-min intervals with periods of quiescence. The spiking activity showed two phases: 1) spike bursts on only 30% of the slow waves; and 2) all slow waves contained spike bursts of maximal duration. The corresponding integrated record for 24-hr fasted rats showed that the duration of the two phases occupied about 2/3 of the total recording time, and the migrating myoelectric complex as a whole occurred three to four times/hr. Intragastric administration of food and amino acids (NaCl, 3.6%, 10 ml; glucose, 8%, 5 ml; amino acids, 450 mM/l, 5 ml) caused continuous irregular spiking for 2 to 3 hr. A similar effect was caused by the food components administered into the duodenum. Oleic acid (0.1 ml) in either the stomach or duodenum caused continuous, but weak, irregular spiking. The velocity of intestinal transit was faster in fasted rats when phenol red (bolus) was administered before a migrating complex than after. The percentage of total bolus emptied by the stomach and each successive segment of the small intestine was approximately 30% and 65% in fed and fasted rats, resp. These data indicate that the presence of nutrients in the stomach and duodenum is capable of inducing a pattern of continuous irregular spiking activity.

6690 POTENTIATION BY COCAINE OF RELAXATIONS OF THE GUINEA-PIG COLON CAUSED BY NORADRENALINE AND BY STIMULATION OF ADRENERGIC NERVES.

(Eng.) Costa, M.; Furness, J. B.; Dawson, K. (Dept. Zoology, Univ. Melbourne, Parkville, Victoria 3052, Australia). *Ajebak* 53(3):223-232, 1975.

The effects of cocaine on the noradrenaline-, isoprenaline-, and inhibitory nerve stimulation-induced relaxations in isolated segments of the guinea-pig distal colon were studied. Cocaine caused a threefold sensitization of the muscle to noradrenaline but no sensitization to isoprenaline. Cocaine (10^{-6} g/ml) also increased the duration, but not the amplitude, of the muscle relaxation observed when branches of the colonic nerves, which carry adrenergic fibers to the colon, were stimulated at frequencies of 1 to 32 Hz in the presence of hyoscine ($6 \cdot 10^{-7}$ g/ml). In the presence of guanethidine, the response was not significantly prolonged by cocaine, but its amplitude was reduced slightly. Cocaine did not affect either the amplitudes or the durations of the responses to intrinsic nerve stimulation in the presence of hyoscine or guanethidine; the relaxation of the colon under intrinsic nerve stimulation has been shown to be due to the activation of nonadrenergic nerves. Fluorescence histochemical studies indicated that the adrenergic nerve terminals lie in Auerbach's plexus, not in the longitudinal muscle. It is concluded that the cocaine-induced sensitization to noradrenaline and the increases in the duration of response to adrenergic nerve stimulation are due to an inhibition of catecholamine uptake into the adrenergic nerves. It appears that even when the neuromuscular separation is large, as in the colon, the concentration of exogenous noradrenaline at the receptors can be decreased by neuronal uptake, and that the uptake mechanism can modify the responses in nerve stimulation *in vitro*.

6691 THE EFFECT OF GLUCOSE AND TETRAETHYLAMMONIUM ON THE PROPULSIVE MOTILITY OF SMALL INTESTINE IN HYPOPHYSECTOMIZED RATS.

(E.) Peng, Y. I.; Peng, M. T. (Coll. Medicine, Natl. Taiwan Univ., Taipei). *J. Formosan Med. Assoc.* 73(8):445-450, 1974.

Blood sugar levels and the propulsive motility of the small intestine were measured simultaneously in tetraethylammonium chloride (TEA)-treated, insulin-hypoglycemic, and hypophysectomized rats to determine the mechanism of increased small intestinal motility after hypophysectomy. Male Long-Evans rats were divided into groups receiving i.p.: 1) saline (1 ml/kg, control); 2) TEA (20 mg/kg); 3) insulin (2 U/kg); 4) insulin and TEA; 5) hypophysectomy with saline; 6) hypophysectomy with TEA; and 7) hypophysectomy with glucose (5%, 20 ml/kg, s.c.). Propulsive motility was determined by tracing the distance traversed by 10% charcoal (1 ml in 10% acasia by stomach tube). After insulin injection the blood sugar levels of the intact rats decreased to the levels of hypophysectomized rats and the motility of insulin-hypoglycemic rats increased to the level of the hypophysectomized rats. After glucose administration the blood sugar level of the hypophysectomized rats rose above normal levels and motility decreased to a value not significantly different from intact animals. Propulsive motility was significantly more rapid in hypophysectomized rats and insulin-hypoglycemic rats than in intact animals. TEA caused a significant decrease in motility in intact, hypophysectomized, and insulin-hypoglycemic rats compared with rats not receiving TEA. However, the motility of TEA-treated hypophysectomized and insulin-hypoglycemic rats was still significantly faster than that of TEA-treated intact rats. These results suggest that the low blood sugar levels of hypophysectomized rats induce increased small intestinal motility.

6692 ANALYSIS OF THE MOTOR EFFECTS OF 13-NORLEUCINE MOTILIN ON THE RABBIT, GUINEA PIG, RAT, AND HUMAN ALIMENTARY TRACT IN VITRO. *(E.)* Strunz, U.; Domschke, W.; Mitznegg, P.; Domschke, S.; Schubert, E.; Wunsch, E.; Jaeger, E.; Demling, L. (Dept. Medicine, Univ. Erlangen-Nuremberg, Krankenhausstrasse 12, D-852, Erlangen, West Germany). *Gastroenterology* 68(6):1485-1491, 1975.

Motor effects of 13-norleucine motilin (13-Nle-M), a synthetic polypeptide analog of motilin, on the contractility of the alimentary tract of rabbit, guinea pig, Wistar rat, and man were investigated *in vitro*. The effects of the drug were limited to specific regions of the gastrointestinal tract. Guinea pig and rat preparations were refractory to 13-Nle-M action. Stomach and upper small intestine muscle strips from the rabbit and man were highly sensitive to the drug; contractile responses were elicited with concentrations of $< 2 \times 10^{-9}$. Although circular muscle from rabbit colon responded to 13-Nle-M, *Taenia coli* preparations were unaffected by the polypeptide; in man the reverse occurred. Gallbladder, uterine, and vascular smooth muscle were unresponsive to 13-Nle-M. Pharmacological analysis revaled that 13-Nle-M acts directly on gastrointestinal smooth muscle and its effects are not mediated *via* nervous pathways. Ganglion blockade by hexamethonium iodide, blockade of axonal conduction by tetrodotoxin, or anticholinergic action by atropine failed to affect the polypeptide actions. It was concluded that 13-Nle-M caused contractions by stimulating receptors on or in muscle cells. Histamine receptors were differentiated from the site of action of 13-Nle-M by the use of the antihistamine pheniramine. The Ca^{++} antagonist compound, verapamil, abolished the contractile response to 13-Nle-M. Thus, 13-Nle-M may be involved in the transport of Ca^{++} to the cytosol of intestinal smooth muscle and cause the initiation of contraction.

6693 ANTIPHOSPHODIESTERASE ACTIVITY AND NONSPECIFIC SMOOTH MUSCLE RELAXATION TESTED ON INTESTINAL SMOOTH MUSCLES. *(E.)* Inatomi, N.; Takayanagi, I.; Takagi, K. (Faculty Pharmaceutical Sciences, Univ. Tokyo, Bunkyo-Ku, Tokyo 113, Japan). *Jpn. J. Pharmacol.* 25(1):63-69, 1975.

The modes of action of papaverine and some nonspecific smooth muscle relaxants on phosphodiesterase were studied. Studies were also carried out to determine whether intestinal smooth muscle relaxation produced by the papaverine-like drugs is mediated by an increase in the intracellular cyclic AMP, which is caused by inhibition of phosphodiesterase. The circular muscle from dog small intestine and the guinea pig taenia coli were used. Extrapolation of double Lineweaver-Burk plots yielded two apparent Michaelis constants (6.7×10^{-6} M and 9.1×10^{-5} M) for cAMP hydrolysis. Similar results were obtained in all enzyme preparations from guinea pig taenia coli and dog small intestine. Papaverine inhibited low K_m enzyme completely. The synthetic antispasmodic drug 1,1-diphenyl-3-piperidinobutanol hydrochloride had little inhibitory action on either enzyme. Caffeine, sodium benzoate, and hydralazine in a 1000 x *g* supernatant of guinea pig taenia homogenate inhibited the low and high K_m enzymes noncompetitively. Papaverine and aminophylline inhibited the low K_m enzyme noncompetitively and the high K_m competitively. The antiphosphodiesterase activities, as negative logarithms of K_i values, of the median effective dose of papaverine almost equaled negative logarithm of its K_i value. There was little correlation between the smooth muscle relaxing activities and the antiphosphodiesterase activities. It is concluded that there are at least two mechanisms for the nonspecific smooth muscle relaxants, one due to the increase of intracellular AMP caused by inhibition of phosphodiesterase, and the other not involved with the intracellular cAMP level.

6694 EFFECT OF PROSTAGLANDIN E_1 ON REACTIVITY OF RAT COLON, INCLUDING THE ROLE OF THE ADRENERGIC SYSTEM. *(Eng.)* Szalaj, W.; Gabryelewicz, A.; Stasiewicz, J. (Inst. Internal Medicine, Bialystok, Poland). *Mater. Med. Pol.* 7(2):99-101, 1975.

The effects of prostaglandin E_1 (PGE_1) on contractile activity and the functional state of adrenergic receptors of the proximal part of the colon in 26 male Wistar rats were studied by drug-induced stimulation and inhibition. PGE_1 administration (1, 10 and 100 µg/ml) caused colon contraction; the magnitude of contraction was dose-dependent. Administration of isoproterenol, a β-adrenergic agonist, 30 sec before PGE_1, produced a decrease in the contractile response (18%). Blocking β-adrenergic receptors with propranol augmented PGE_1-induced contraction (20%). Stimulation and inhibition of α-adrenergic receptors with L-phenylephrine hydrochloride and phentolamine, resp., produced insignificant changes in the response to PGE_1 (only a slight decrease in contraction). It is concluded that β-receptors have a stronger inhibiting influence than α-receptors and that the functional state of the adrenergic system, particularly the β-receptors, modifies the contractile response to PGE_1.

6695 EFFECT OF TWO METHYLATED PROSTAGLANDIN E$_2$ ANALOGUES ON GASTRODUODENAL PRESSURE IN MAN.

(E.) Nylander, B.; Andersson, S. (Karolinska Hosp., Stockholm, Sweden). *Gut* 15(11):91-95, 1974.

The effects of two methylated analogues of prostaglandin E$_2$(PGE$_2$), 16,16-dimethyl PGE$_2$ and 15(S)-15-methyl ester, on gastrointestinal motor activity was studied in five healthy men. The intraluminal pressure in the pyloric antrum and in the duodenum was recorded using small rubber balloons tied to a polyethylene tube; they were filled with water, and pressure was continuously recorded on a Rikadenki 3-channel recorder. Two types of experiments were performed. In the first, the subjects fasted overnight, and swallowed the balloon taped onto a Beckman glass electrode, the tip of which was positioned in the descending part of the duodenum *via* fluoroscopy. After a test meal (200 ml of meat bouillon), 80μg of 16,16-dimethyl PGE$_2$ was swallowed, followed by an identical test meal; subsequent pressure recordings revealed no significant changes in the motor response. However, p.o. administration of 140μg of the analogue completely inhibited motor activity in both the stomach and the duodenum. In an additional experiment, pressure recordings were made on two subjects during secretory tests after duodenal administration of 80 or 100μg of 15(S)-15-methyl PGE$_2$ methyl ester. Gastric secretion was continually stimulated by i.v. infusion of pentagastrin, and the gastric juice periodically collected. The balloon, located in mid duodenum, revealed almost complete inhibition of the duodenal motor activity in each instance. The lack of detectable effect of the 80μg dose of 16,16-dimethyl PGE$_2$ was noted, despite previous reports of the dose producing a marked inhibition (70%) of acid secretion. It is suggested that the PGE$_2$ analogue inhibited duodenal, as well as gastric, pressure by a similar direct effect on the smooth muscle, as had been recorded *in vitro*.

6696 EFFECT OF 16,16-DIMETHYL PGE$_2$ ON GASTRIC EMPTYING AND INTESTINAL TRANSIT OF A BARIUM-FOOD TEST MEAL IN MAN.

(E.) Nylander, B.; Mattsson, O. (Karolinska Hosp. S-104 01, Stockholm 60, Sweden). *Scand. J. Gastroenterol.* 10(3):289-292, 1975.

The effect of 140 μg of 16,16-dimethyl prostaglandin E$_2$ (16,16-dimethyl PGE$_2$) on gastric emptying and intestinal transit of a barium-food mixture was studied in eight healthy adult males. Transport of the test meals from stomach to colon was followed by low dose fluoroscopy with repeated photographic recording (every 15 min during the first two hr after ingestion and then every half hr for an additional 1.5 hr). 16,16-Dimethyl PGE$_2$ significantly enhanced the rate of gastric emptying; the mean emptying times with and without this compound were 34 and 74 min, resp. In addition, food-contrast medium appeared sooner in the colon following 16,16-dimethyl PGE$_2$ administration. After administration of 16,16-dimethyl PGE$_2$ in five subjects, the duodenum and the first part of the jejunum appeared flaccid and dilated. It is postulated that the more rapid emptying of the stomach after administration of 16,16-dimethyl PGE$_2$ is due to a decreased duodenal resistance to the gastric outflow. Thus, the earlier appearance of contrast in the colon could be partially due to the more rapid gastric emptying following 16,16-dimethyl PGE$_2$ administration.

6697 INFLUENCE OF SULPIRIDE ON GASTROINTESTINAL MOTILITY. EXPERIMENTAL RADIOLOGICAL STUDY IN THE DOG.

(E.) Boccadero, B.; Leonardi, L.; Calvari, A. R. (Inst. Veterinary Radiology, Univ. Milan, Italy). *Arzneim. Forsch.* 25(6):905-916, 1975.

The effect of N-ethyl-2(2-methoxy-5-sulfamido-benzamido-methyl)-pyrrolidine (sulpiride) on gastrointestinal motility during radiological examinations was studied in nine dogs. The drug was administered in a single dose either immediately after or 10 min before the barium meal. Sulpiride was given: i.v., 0.25 to 10 mg/kg; i.m., 1 to 4 mg/kg; p.o., 2.5 to 25 mg/kg (syrup); or p.o., 5 to 10 mg/kg (capsule). Over a period of 9 mo, 92 complete radiological examinations of the gastrointestinal tract were carried out. Generally sulpiride accelerated transit time and the optimal doses were: i.v., 1 mg/kg; i.m., 2 to 4 mg/kg; and syrup and capsule, 5 to 10 mg/kg. Strong, multiple peristaltic waves from the cardia towards the pylorus, consistent with the expression of gastric hyperkinesia, were seen in the stomach after sulpiride administration. A general increase of tonic activity and phasic activity, mainly of a propulsive type, was seen in the duodenum. Varying effects of the drug were seen in the jejunum and ileum which were independent of dosage or route of administration. These effects included: generalized hypertonia, generalized hypotonia and some periods of dystonia. The reaction in the colon was variable, including normal, segmentary or total hypertonia, or sometimes mild hypotonia. It is suggested that sulpiride be used in radiological examinations due to its effects on normal smooth gastrointestinal musculature.

6698 THE EFFECT OF DUODENAL INFUSION ON THE ELECTROMYOGRAM OF GASTRIC MUSCLE DURING ACTIVATION AND INHIBITION OF GASTRIC EMPTYING.

(E.) Bell, F. R.; Grivel, M. (Royal Veterinary Coll., London, N.W. 1, England). *J. Physiol.* 248(2):377-391, 1975.

The effects of duodenal infusions of HCl and sodium bicarbonate on the activity of the gastric musculature were studied in conscious Friesian bull calves by recording the e.m.g. from antrum and fundus and simultaneously measuring the output of a test meal from the stomach. The test meals consisted of sodium bicarbonate, HCl, or distilled water with phenol red as a marker. E.m.g. recordings were made from the lesser and greater curvature of the fundus, from the antrum and pylorus of the abomasum, and from the duodenum; recordings were made before the onset of duodenal infusion, during duodenal infusion, and during simultaneous duodenal infusion and test meal administration. When the abomasum was partially distended by the water and bicarbonate, but not the HCl test meals, rhythmic motility was readily recorded from the e.m.g. of the smooth muscle of the fundus and antrum; the rhythmic contractions of the antrum during gastric evacuation of the meal were reinforced by both rhythmic and tonic fundic contractions. The output volume of the stomach was directly correlated with the e.m.g. activity. The intragastric fluid was generally emptied in gushes coinciding with a strong contraction of the antrum; however, during periods of antral activity after ingestion of the HCl test meal, the fluid was evacuated *via* the force generated by persisting rhythmic fundic contractions. Using reentrant cannulas so that the duodenum could be infused separately from the gastric effluent, isotonic sodium bicarbonate produced almost 100% gastric evacuation with greatly enhanced e.m.g. activity of the fundus and antrum. Duodenal HCl produced the opposite effect, the gastric muscle becoming quiescent and 100% of the gastric test meal being retained. The data show that the activating or inhibitory effects of a duodenal infusate are produced through an activating or inhibitory effect on the smooth muscle of the stomach. The mechanism of the interrelationship between duodenal receptor and gastric effector is unclear, but the connection is not intramural since it continued when the duodenum was transected near the pylorus.

6699 EFFECT OF HEMORRHAGE ON MYOELECTRIC ACTIVITY OF STOMACH AND DUODENUM IN DOGS. *(E.)*

Kowalewski, K.; Zajac, S. (Surgical-Medical Res. Inst., Univ. Alberta, Edmonton, Alberta, Canada). *Surg. Gynecol. Obstet.* 141(2):227-231, 1975.

Systemic arterial hemorrhage was induced in male mongrel dogs, and the myoelectric activity of the stomach and duodenum during and after loss of blood was recorded. Dogs with previously implanted gastric and duodenal electrodes were used. A marked decrease in arterial blood pressure was observed in all dogs after each bleeding, although the effect was different in each dog. In all dogs, blood pressure fell to 0 mm of Hg after 75% blood loss. The average frequency of electrical control activity/min was 4.8 for the stomach and 18.9 for the duodenum, during the 30-min period preceding bleeding. Progressive loss of blood volume was accompanied by progressive deterioration of electrical recordings. The blood removed after four bleedings (60% total volume) was retransfused in 25 min. There was a simultaneous return of arterial blood pressure and electrical control activity to normal. Irregular bursts of spikes occurred in all stomachs after the third or fourth bleeding, which lasted for no more than 2 min and were associated with antral contractions. Hemorrhage induced major changes in some blood values, such as: pH, after bleeding 7.08 (before, 7.38); hemoglobin, 10.8 g% (11.9 g%); bicarbonate, 13.2 mEq/l (20.6 mEq/l); arterial pO_2, 53.1 mm Hg (82.0 mm Hg); venous pO_2, 26.0 mm Hg (34.0 mm Hg); arterial pCO_2, 24.0 mm Hg (33.4 mm Hg); and venous pCO_2, 55.1 mm Hg (30.6 mm Hg). These results confirm the importance of a time factor in the development of the metabolic effects of hemorrhage.

6700 EXPERIMENTAL ESOPHAGITIS IN CATS IMPAIRS LOWER ESOPHAGEAL SPHINCTER PRESSURE. *(E.)*

Eastwood, G. L.; Castell, D. O.; Higgs, R. H. (United States Naval Hosp., Philadelphia, Pa.). *Gastroenterology* 69(1):146-153, 1975.

The histological appearance of the lower esophagus was compared with lower esophageal sphincter (LES) pressure measurements, before and during the development of experimental esophagitis, as well as after a period of healing. All cats underwent baseline LES pressure measurements and mucosal suction biopsies. After 1 week, on each of 4 consecutive days, LES pressure was determined. A manometry tube was either then withdrawn or advanced 5 cm, and either the esophagus or stomach was perfused with 0.1 N HCl or distilled water, at the rate of 1.1 ml/min. On day 5, LES pressure was recorded and mucosal biopsies were taken. At the end of a 3.5-week recovery period, LES pressure and mucosal biopsies were again obtained. All initial biopsies were normal. Severe esophagitis developed in all five cats receiving 0.1 N HCl for 1 hr/day. Biopsy during the perfusion period in these animals showed an architecturally nondescript mass of inflammatory tissue devoid of surface epithelium. After the healing period, two of these five developed strictures; the surface epithelium had regenerated in the remaining three. After 4 days of esophageal perfusion for 0.5 hr/day, inflammatory changes were produced in all three cats in this group, although these changes were not so severe as those found in the first group. Mucosal edema and neutrophilic infiltration were also evident. All biopsies were normal after recovery. Controls receiving water or HCl in the stomach showed no mucosal abnormalities. There was no difference in mean LES pressure in the four groups before induction of esophagitis. LES pressure began to drop in the first group by perfusion day 2, and mean LES pressures on days 4 and 5 were significantly lower than basal values. A similar but less rapid fall occurred in LES pressures of cats in the second group. These results show that profound reductions in LES pressures are associated with the development of esophageal inflammation in cats, and that LES pressure returns to normal upon resolution of the inflammation.

6701 EFFECT OF ACUTE ISCHEMIA ON THE MOTILITY OF THE SMALL BOWEL IN THE AWAKE DOG. *(E.)*

Guisan, Y. J.; Hreno, A.; Gurd, F. N. (Montreal General Hosp., Montreal, Quebec, Canada). *Eur. Surg. Res.* 7(1):23-33, 1975.

A method was designed to allow the study of the small intestine motility response in intraluminal mucosal stimulation after ischemia in a 30-cm loop of the upper jejunum of mongrel dogs (26-28 kg). The effect of acute ischemia was obtained by clamping the feeding arteries. Studies were performed on the awake dog in order to eliminate anesthetic side-effect. A jejunostomy with a Roux-en-Y anastomosis for reestablishment of intestinal continuity was constructed to gain access to the upper jejunum. The jejunal segment proximal to the anastomosis was brought out through the skin. The motility was estimated after mucosal stimulation with a standard bolus of isotonic 0.1 N HCL (5 ml). Stimulation occurred every eight min and the time lag between stimulation and response, frequency, maximum and mean amplitude, and number of contractions were considered. This technique possessed high reproducibility; a typical response followed 42 of 45 bolus injections. Acute ischemia caused an immediate hyperexcitability of the jejunum section under study, despite a complete destruction of the mucosa, followed by an irregular hyperexcitable pattern during the first 48 hr after injury. The controls presented a strongly diminished response to stimulation with a slow recovery. The hyperexcitable state which results after ischemia may mask more subtle changes in motility regulation which would be a consequence of specific mucosal damage.

6702 EFFECT OF A SEROTONIN ANTAGONIST (PCPA) ON THE DUMPING SYNDROME IN GASTRECTOMIZED DOGS. *(E.)* Bucholz, R. W.; Storer, E. H. (Veterans Admin. Hospital, West Haven, Conn.). *Surg. Forum* 24:414-416, 1973.

A recently discovered specific serotonin antagonist parachlorophenylalanine (PCPA) was used to study the role of serotonin release from the bowel in the gastrointestinal component of the dumping syndrome. Sixty percent gastric resections were performed on 10 dogs, and dumping was induced by instillation of a hypertonic glucose-barium meal through an orgastric tube. Criteria used to determine the presence of dumping included characteristic physical signs of dumping, fluoroscopic determination of bowel hypermotility, and serial roentgenograms. Dumping was easily induced in the gastrectomized dogs. However, s.c. administration of PCPA (75 mg/kg/day) for eight days successfully eliminated any signs of dumping after instillation of a hypertonic glucose-barium meal, and resulted in an average decrease in small-bowel serotonin to 10% of normal levels. Unlike previously studied antagonists, PCPA was a specific, potent inhibitor of serotonin synthesis, acting through inhibition of the rate-limiting enzyme tryptophan hydroxylase. Its role of an effective depletor of bowel serotonin, in the absence of side-effects on the metabolism of other biologic amines, is further evidence for a role of serotonin in the gastrointestinal component of the postgastrectomy dumping syndrome.

SECRETION AND METABOLISM

6723 EFFECT OF CROMOLYN SODIUM AND DEUTERIUM OXIDE ON ANAPHYLACTIC HISTAMINE RELEASE FROM RAT PERITONEAL MAST CELLS IN VITRO. *(Eng.)* Herzig, D. J.; Kusner, E. J. (Warner-Lambert Res. Inst., Morris Plains, N. J. 07950). *J. Pharmacol. Exp. Ther.* 194(2):457-462, 1975.

The effect of deuterium oxide and cromolyn sodium on anaphylactic histamine release from rat peritoneal mast cells was studied *in vitro*. Mast cells from 6-wk-old male Sprague-Dawley rats were sensitized *in vitro* with rat reaginic antiovalbumin and challenged with ovalbumin, D_2O, and/or cromolyn sodium. After 5 min, the cells were removed from the medium, which was assayed for histamine using fluorometric techniques. At 37 C, D_2O caused a concentration-dependent potentiation of anaphylactic histamine release from the mast cells; there was a 1.3-fold potentiation with 5% (v/v) D_2O and a three-fold potentiation at 25% D_2O (v/v). At these concentrations, D_2O had no effect on spontaneous histamine release. The high rate of histamine release in 25% D_2O was not attributed to mast cell destruction, as trypan blue was actively excluded by the cells under these conditions. When the sensitized cells were challenged with antigen at 25 C in the presence and absence of D_2O, the D_2O proportionately increased both the rate of histamine release and the total amount of histamine released, so that half-time of release was not affected by D_2O. The concentration of cromolyn sodium required to obtain 50% inhibition of histamine release increased from 6 μM without D_2O to 80 μM in 10% D_2O and to greater than 500 μM in 25% D_2O. However, the graph showing the relationship between cromolyn sodium concentration and percent histamine release was not shifted in a parallel manner by D_2O. This suggests that the interaction between D_2O, cromolyn sodium, and the histamine-releasing processes of mast cells is not a simple one.

6724 STUDIES ON THE CALCEMIC EFFECT OF INTRAVENOUS SECRETIN IN HUMANS. *(E.)* Schwille, P. O.; Scholz, D.; Samberger, N. M.; Kayser, P. E. (Mineral Metabolism Lab., Univ. Erlangen-Nürnberg, Erlangen, West Germany). *Acta Hepato-Gastroenterol.* 22(3):195-200, 1975.

To elucidate the nature of observed hypercalcemia after secretin administration, patients with duodenal ulcer (Group 1), primary hyperparathyroidism (Group 2), one case of excluded antrum, and normal subjects were evaluated after infusion of pure, natural secretin (3 U/kg/hr), after a 12-hr fast. The average control increment in total Ca was 0.45 mg/100 ml after 45 min of infusion; Groups 1 and 2 had increments of 0.75 mg/100 ml after 90 min of infusion. A highly significant correlation was found between protein-bound Ca and total protein in Group 1 only. Inorganic plasma P dropped slightly in Group 2 and in controls, but remained stable in Group 1. Baseline-ionized Ca values remained stable in all groups. A slight but significant mean fall in gastrin was seen in controls and in Group 1.

Group 2 had a slight rise in gastrin, but this could be due to a variance in the assay procedure. The integrated gastrin response revealed no difference between the groups. All subjects had a small rise in glucagon; values for Group 2 were significantly higher than controls. Integrated glucagon showed that α cells in Group 2 maintained a high hormone output. Urinary excretion of P, Ca, and Na were normal in controls and in Group 1, and higher in Group 2 (as expected). Together with the data from the patient with excluded antrum, it is concluded that the hypercalcemic effect of secretin is not mediated by Ca regulatory hormones, but must be of an unspecific nature.

SECRETION AND METABOLISM

Stomach

6728 ARE NON-ABSORBABLE INDICATORS OF COMPARABLE VALUE IN THE HUMAN STOMACH MADE ABNORMAL BY TAUROCHOLIC ACID? *(E.)* Ivey, K. J.; Parsons, C. (R. Prince Alfred Hosp., Sydney, Australia). *Clin. Exp. Pharmacol. Physiol.* 2(2):151-157, 1975.

Chromium-51 ($^{51}CrCl_3$) and phenolsulfonphthalein (phenol red) were compared as nonabsorbable indicators of gastric secretion and emptying in the human stomach before and after alteration of the ionic permeability of the gastric mucosa by taurocholate. Nasogastric tubes were positioned in the fasting stomachs of healthy male volunteers and a 200 ml portion of test solution containing 160 mM HCl, phenol red, $^{51}CrCl_3$, and polyethylene glycol (PEG) was introduced; in some tests, the test solution also contained 10 mM taurocholic acid. The indicators were measured in the original test solution and in gastric aspirates obtained immediately after ingestion of the test solution and at intervals 15 and 30 min later. The ratios of the initial and final concentrations of the indicators (C_i:C_f) were compared. Correlation coefficients of the C_i:C_f ratios for $^{51}CrCl_3$ and phenol red were 0.91 in the control studies and 0.75 after taurocholic acid instillation; there was no significant difference with either indicator. During taurocholic acid instillation, the C_i:C_f values tended to fall in comparison with the control values. In a smaller number of subjects in whom PEG was also measured, the results were similar to those obtained with $^{51}CrCl_3$ and phenol red. The results therefore indicate that $^{51}CrCl_3$, phenol red, and PEG are comparable indicators in the normal human stomach and in the stomach made abnormal by a lipid-soluble agent such as unionized tarurcholic acid, although the correlation between indicators is reduced in the abnormal stomach. No evidence of increased absorption of any indicator was found in spite of the increased ionic permeability produced by taurocholic acid.

6729 RADIOAUTOGRAPHIC AND QUANTITATIVE STUDIES ON PARIETAL AND PEPTIC CELL KINETICS IN THE MOUSE. *(E.)* Willems, G.; Lehy, T. (Hopital Bichat, Paris, France). *Gastroenterology* 69(2):416-426, 1975.

Radioautography after *in vivo* labeling with (^{3}H)thymidine (1 μc/gm, i.p. on the third, fourth, and fifth days) was used to estimate DNA synthesis in progenitor cells and parietal and peptic cell proliferation during the chronic administration of natural gastrin (10 μg in 0.2 ml saline s.c. every 8 hr for 20 days) to male Swiss albino mice. The stomachs were examined 0-14 days after the last (^{3}H)-thymidine injection. The gastrin-treated mice did not differ from a group of saline-treated controls in terms of body weight gain, and no macroscopic or microscopic ulcers were seen in the gastric mucosa at the time of death. At 0 days after the termination of (^{3}H)thymidine treatment, few labeled parietal cells were seen in either the gastrin-treated or control mice; most labeled cells were undifferentiated or mucous cells. Thereafter, the population of labeled parietal cells increased significantly, reaching a peak level (254.15 labeled cells/5000 parietal cells) on the fifth day after termination of (^{3}H)thymidine treatment in the controls and on the third day in the gastrin-treated animals. In comparison with the controls, there was a 1.27% excess production of new parietal cells/day in the gastrin-treated animals, and after 20 days of gastrin treatment there was a 20% excess in total parietal cells. More than 95% of the new cells in both groups originated in the "superficial parietal cell area." The controls and gastrin-treated mice did not differ in terms of the proliferative activity of the peptic cells; the ratio of peptic cells to parietal cells was significantly reduced in the gastrin-treated mice at the termination of gastrin treatment. The data indicate that more than 95% of the parietal cells originate from the differentiation of immature progenitor cells in the neck area of the glands and that most peptic cells are renewed through cell replication of other peptic cells. Gastrin augments the production of parietal cells *via* acceleration of the maturation process of progenitor cells into parietal cells, increased duplication of progenitor cells, and augmentation of the proportion of stem cells being transformed into parietal cells.

6730 EFFECT OF PROLONGED ADMINISTRATION OF HOMOLOGOUS AND HETEROLOGOUS INTRINSIC FACTOR ANTIBODIES ON THE PARIETAL AND PEPTIC CELL MASSES AND THE SECRETORY FUNCTION OF THE RAT GASTRIC MUCOSA. *(E.)*

Inada, M.; Glass, G. B. J. (New York Medical Coll., New York, N.Y. 10029). *Gastroenterology* 69(2):396-408, 1975.

To determine the effects of circulating intrinsic factor antibodies (IFA) on gastric morphology and secretory function, female Sprague-Dawley rats were given daily i.v. injections of immunoglobulin G (IgG, 4 mg in 0.5 ml of normal saline). The IgG fractions were separated on DEAE cellulose columns from sera of patients with pernicious anemia, containing both IFA and parietal cell antibodies (PCA); sera from patients with atrophic gastritis, containing PCA only; or sera from rabbits immunized with semipurified human or rat IF. Control rats were treated with saline or IgG processed from normal human or rabbit sera, or were untreated. One-third of each group was intubated biweekly after fasting and histamine stimulation (0.1 mg/kg, s.c.) and the hourly output of HCl, pepsin, and IF were determined. At the end of the experiment, the rats were killed and the mucosal surface and thickness were measured; the parietal cell and peptic cell masses were counted at the same time. In the control groups, there was either no change or a progressive growth in the cellular mass of the gastric mucosa; the latter was accompanied by no change or an increase in the HCl, pepsin, and IF outputs. In contrast, the rats injected with IgG containing IFA to human or rat IF showed a statistically significant thinning of the gastric mucosa, a reduction in peptic cell number, and corresponding decreases in the output of pepsin and IF. The latter were reduced 50% from the initial values and 62 and 75%, resp., when compared with the normal human and rat IgG-injected controls. In animals injected with the IgG fractions from the pernicious anemia sera, the output of IF, pepsin, and HCl was significantly decreased, as were the peptic and parietal cell masses. Thinning of the gastric mucosa, a reduction in the parietal cell mass, and a significant decrease in the HCl output were observed in the rats injected with the atrophic gastritis IgG; the outputs of pepsin and IF were also significantly reduced in these animals. The data suggest the participation of humoral immunological mechanisms in the production of gastric atrophy and secretory failure.

6731 UNIQUE ENZYMES OF PURIFIED MICROSOMES FROM PIG FUNDIC MUCOSA: K$^+$-STIMULATED ADENOSINE TRIPHOSPHATASE AND K$^+$-STIMULATED pNPPase. *(E.)*

Forte, J. G.; Ganser, A.; Beesley, R.; Forte, T. M. (Dept. Physiology-Anatomy, Univ. California, Berkeley, Calif. 94720). *Gastroenterology* 69(1):175-189, 1975.

The microsomal fraction from pig fundic gastric mucosa was assayed for the presence of K$^+$-stimulated ATPase and K$^+$-phosphatase activities. The microsomal fraction was isolated by differential centrifugation and density gradient fractionation. In addition to the enzyme assays, determinations of the microsomal protein content and RNA were made, and the membrane fractions were studied by electron microscopy. The microsomal fractions showed high levels of K$^+$-stimulated ATPase and K$^+$-stimulated phosphatase activity, while similar preparations from antral mucosa showed virtually no such activity. A low density band of membranes from the fundic preparations (peak 1.12-1.13 g/ml) possessed all of the K$^+$-stimulated enzyme activities. The morphological features and abundant glycoproteins of this fraction suggested that the low density microsomes might be derived from the tubulovesicles of oxyntic cells. Mitochondrial and ribosomal markers were associated with membranes with much higher densities (greater than 1.22 g/ml). The K$^+$-stimulated ATPase showed a pH optimum of 7.5 and required Mg^{++}, but neither Na$^+$ nor ouabain had any appreciable effect on the activity. K$^+$ stimulation of basal ATPase ranged from 1.5 to 3.0-fold with an apparent K_a for activation between 0.2 and 0.4 mM of K$^+$. The addition of various K$^+$ ionophoretic substances such as gramicidin resulted in up to 6-fold stimulation of the basal K$^+$-ATPase activity. The mean activities of seven separate preparations of purified low density pig fundic microsomes were (μM of ATP hydrolyzed/mg of protein/hr): basal ATPase, 15.8; basal ATPase plus 10 mM of K$^+$, 29.3; plus 10 mM of K$^+$ and 10^{-5} M of gramicidin, 45.2. Neither the basal ATPase nor the K$^+$-stimulated activities were altered by HCO$_3^-$ or Cl$^-$. The occurrence of these unique enzyme activities in the oxyntic region of the gastric mucosa suggests some relation with secretory activity, but further research is needed to elaborate the physiological function of this gastric system.

6732 MECHANISMS FOR CATECHOLAMINE DISENGAGEMENT FROM VARIOUS PARTS OF THE STOMACH AND THEIR ACCUMULATION IN GASTRIC TISSUE. *(Rus.)*

Mirzoian, S. A.; Virabian, T. L. (Erevan Med. Inst., USSR). *Zh. Eksp. Klin. Med.* 14(2):3-8, 1974.

The content of adrenalin and noradrenalin was compared in the blood flowing from the lesser and greater curvatures of the stomachs of dogs and in the walls of the isolated stomachs of rats under the influence of various doses of quateron and acetylcholine. The motor function of the lesser and greater curvatures of the stomach was recorded by an electrogastrograph with a set of platinum electrodes.

The content of adrenalin and noradrenalin was determined spectrofluorometrically. Results showed that i.v. introduction of acetylcholine (5 μg/kg), small doses of quateron (0.2 mg/kg), and irritation of the vagus nerve (by faradization) together with the enhancement of motor function of the stomach increased the catecholamine content in the blood, in the stomach, and in the tissues of the stomach walls. Larger doses of quateron (2 mg/kg) promoted the accumulation of catecholamines in tissues of the stomach walls, but inhibited the motor activity of the stomach and reduced the contents of adrenalin as well as of noradrenalin in the blood and in the stomach. This double effect of high doses of quateron is attributed to quateron's cholino-positive influence as a result of which the larger doses of quateron promote accumulation of catecholamines in tissues of stomach walls, simultaneously suppressing their disengagement from the stomach tissue.

6733 METABOLISM OF SYNTHETIC HUMAN GASTRIN AND DNS-GASTRIN IN RATS AND MICE. *(E.)* Matsuyama, T.; Kodama, M.; Nagao, Y. (Hiroshima Univ. Sch. Medicine, Japan). *Hiroshima J. Med. Sci.* 23(2/3):155-164, 1974.

The metabolism of synthetic human gastrin (SHG) and DNS-gastrin was studied in DDY mice and Wistar rats. ^{3}H-SHG (15 mg/kg) was injected into the tail veins of conscious mice and the animals were frozen 10 or 30 min later. The mice were then sectioned and examined by whole body autoradiogram. The experiment was repeated following the i.v. administration of ^{14}C-DNS-gastrin (1.3 mg/kg). In the second experiment, ^{3}H-SHG (200 μg/kg) was injected i.v. into normal rats and animals which had undergone bilateral nephrectomy; ^{14}C-DNS-gastrin was similarly injected into normal rats and animals which had undergone bile duct ligation. Blood was withdrawn 1 to 360 min after injection and its radioactivity determined. In a third experiment, ^{3}H-SHG (2.5 μg/kg) was injected i.v. into Wistar rats and the bile and urine were collected at 10 min intervals and respective radioactivities were determined. In the first experiment, strong radioactivity was seen in the renal cortex, renal pelvis, bladder contents, bladder mucosa, and gallbladder 10 min after ^{3}H-SHG injection. After 30 min, the concentration of label in the bladder contents and gallbladder had increased, but the activity in the renal cortex and liver was still strong. Ten min after ^{14}C-DNS-gastrin administration, there was a large amount of radiation in the liver, and after 30 min the gallbladder was markedly distended with strongly radioactive bile; there were also marked accumulations of activity in the kidney and bladder contents. In the second experiment, radioactivity tended to be retained in the blood longer in the nephrectomized rats than in the normal rats. The retention of radioactivity in the blood of the bile duct-ligated group was also markedly prolonged. In the third experiment, 44.9% of the total radioactivity was eliminated from the body within 3 hr; 33% was excreted in the urine and 11.9% was excreted in the bile. The data indicate that SHG is metabolized in the urinary system, mainly in the renal cortex, and that DNS-gastrin is primarily metabolized in the liver and bile duct.

6734 SYNTHESIS AND SECRETION OF PROTEIN AND PEPSINOGEN BY RABBIT GASTRIC MUCOSA IN ORGAN CULTURE. *(E.)* Sutton, D. R.; Donaldson, R. M., Jr. (Boston Univ. Sch. Medicine, Mass.). *Gastroenterology* 69(1):166-174, 1975.

The active synthesis and secretion of proteins, including pepsinogen, by gastric mucosal biopsies *in vitro* are reported. Mucosal biopsies were obtained from the stomachs of white New Zealand rabbits. To assess incorporation of amino acid into tissue protein, L-[1-^{14}C]leucine (2 μCi) was added to each ml of culture medium. Secretion of labeled proteins was studied by centrifugation and dialyzation, or in pulse-chase experiments with 5 μCi/ml of [^{14}C]leucine. Incorporation of radioactivity into tissue protein was linear with time up to 24 hr in continuous cultures; secretion was also linear after an initial lag of 3 to 6 hr. Biopsies cultured in an isotope-free medium and then transferred to a labeled medium showed the same rate of incorporation as in freshly-excised biopsies. Incorporation of radioactivity was inhibited 96% by cycloheximide at 0.5 mg/ml for 1 hr, and by 99% for 24 hr. Total pepsin activity in cultured biopsies did not decrease, but a linear increase was seen in the culture medium, at 24 hr corresponding to 40% of that originally present in the biopsies. Gel electrophoresis showed a single major peak of radioactivity approximating the position of a stained band of protein obtained during electrophoresis of hog pepsin. This also corresponded to the peak obtained by gel filtration. Ion exchange chromatography showed four peaks, each of which coincided with pepsin activity. Acetylcholine markedly stimulated secretion of labeled protein and pepsinogen. Acetylcholine, pentagastrin, secretin, and the octapeptide of cholecystokinin (in 10^{-10} M concentrations) stimulated protein secretion. Overall incorporation of radioactivity was stimulated by 10^{-9} M pentagastrin. These data indicate a direct *in vitro* effect of pentagastrin on protein synthesis, and suggest the *de novo* synthesis of pepsinogen by isolated gastric mucosa.

6735 IN VITRO INCORPORATION OF $^{35}SO_4$ INTO RAT GASTRIC POLYANIONS AND THEIR DEGRADATION BY GASTRIC ENZYMES. *(E.)* Liau, Y. H.; Horowitz, M. I. (New York Medical Coll., Valhalla, N.Y. 10595). *Digestion* 11(5-6):370-381, 1974.

The *in vitro* incorporation of ^{35}S-sulfate into gastric polyanions was studied using whole stomach (mucosa and muscle) and cartilage from a male Sprague-Dawley rat. Pieces of this tissue were incubated for 16 hr in Joklik-modified minimum essential medium containing 100 μCi $Na_2{}^{35}SO_4$. The gastric polyanions from the stomach tissue, incubation medium, and rib-cartilage were subsequently fractionated and the fractions analyzed by thin-layer chromatography, cellulose acetate electrophoresis, paper electrophoresis, and scintillation counting. The sulfatase activity of crude gastric enzyme toward each fraction was also determined. ^{35}S-sulfate was incorporated into the acidic mucopolysaccharides, various glycoprotein fractions, and sulfatides of the tissue and medium. More radioactive sulfate was incorporated into the soluble and medium components than into the tissue-bound components, and the distribution of ^{35}S in stomach fractions was quite different from that in rib fractions. Detergent fractionation and electrophoresis suggested the presence of sulfated polyanions not previously described for this tissue. In the studies with crude gastric enzyme, inorganic sulfate was liberated only from the fractions containing chondroitin sulfates. The gastric enzyme also liberated organic sulfates from chondroitin sulfates and from sulfated glycoproteins. The results suggest that sulfation in the stomach tissue occurred in a wide variety of polyanions besides the chondroitin sulfates, that partial desulfation of the chondroitin sulfates had occurred before isolation from the tissue, that a significant mucolytic action may occur in stomach tissue, and that the majority of ^{35}S-labeled substances were probably composed of glycoproteins.

6736 VITAMIN B_{12}-BINDING PROTEINS IN HUMAN GASTRIC MUCOSA: GENERAL PATTERN AND DEMONSTRATION OF INTRINSIC FACTOR ISOPROTEINS TYPICAL OF MUCOSA. *(E.)*

Marcoullis, G.; Gräsbeck, R. (Minerva Foundation Inst. Medical Res., P. O. Box 819, SF-00101, Helsinki 10, Finland). *Scand. J. Clin. Lab. Invest.* 35(1):5-11, 1975.

The nature of intrinsic factor in human gastric mucosa was studied. Submucosal and mucosal homogenates were prepared from stomach specimens taken at surgery. Only macroscopically normal-appearing tissue was used. Samples were analyzed by gel filtration, cellulose column chromatography and isoelectric focusing. For logical indentification of vitamin B_{12}-binding proteins, a serum from a patient with pernicious anemia with antibodies binding the B_{12}-intrinsic factor complex and a rabbit antiserum against a crude preparation of a B_{12}-binding protein were used. Sedimentation coefficients were also estimated. After gel filtration of 2 to 3 ml samples of mucosal extracts, radioactive peaks were identified as the B_{12} complexes of R protein and intrinsic factor. The B_{12}-intrinsic factor peak disappeared after addition of pernicious anemia and rabbit antisera. A small quantity of transcobalamin II was also detected. The molecular weight of the mucosal complex was shown to be about 1,400 daltons less than that of the gastric juice complex. Isoelectric focusing showed that mucosal extract contained components with pI's that were closer to neutral than to those of gastric juice. The presence of these neutral components (N-components) was also demonstrated by column chromatography. After isoelectric focusing, one N-component resolved into components isoelectric at pH 5.95, 6.25 and 6.52. Simultaneous centrifugation of mucosal and gastric juice B_{12}-intrinsic factor complexes showed no difference in sedimentation rate. When they were centrifuged together with leukoagglutinin, a sedimentation coefficient of 4.1S was obtained for the B_{12}-intrinsic factor complex. It is suggested that the intrinsic factor isoprotein phenomenon in gastric juice and mucosa is best explained by a similar polypeptide chain binding carbohydrate chains, which vary in sialic acid composition and also with respect to other carbohydrates.

6737 A HISTOCHEMICAL APPROACH TO THE CHOLINERGIC INNERVATION OF ENDOCRINE-LIKE CELLS IN DOG ANTRO-PYLORIC MUCOSA. *(E.)*

Yamaguchi, I.; Mori, J.; Honda, F.; Nishizaki, H.; Kumada, S. (Fujisawa Pharmaceutical Co. Ltd., Yodogawa-Ku, Osaka, Japan). *Jpn. J. Pharmacol.* 24(5):721-728, 1974.

The cholinergic innervation of endocrine-like cells was studied in such a way so that the cells and the acetyl cholinesterase activity were demonstrated by formaldehyde-HCl treatment and the acetylthiocholine method, resp. The cholinergic innervation of endocrine-like cells in the antropyloric areas was compared with that of exocrine cells in the fundic gland. Tissue sections were taken from the stomachs of anesthetized mongrel dogs. Sections were fixed, stained and examined by fluorescence and light microscopy. Acetyl cholinesterase staining showed cholinergic nerve fibers with a wide distribution in the fundic mucosa, especially in the middle area. Nerve fibers were also seen in close proximity to the base of secretory cells, a few in the superficial 1/5 of the mucosa and large bundles emanated from the submucosa. In comparison, chief cells were arranged in a single layer around the gastric lumen, and were distributed in the lower 2/3 of the mucosa. The arrangement of parietal cells was similar. Most cholinergic nerve fibers were distributed in the basal 1/2 or 1/3 of the antropyloric mucosa, and stained more lightly for acetyl cholinesterase activity than those in the fundic mucosa. Transverse sections of pyloric glands were surrounded by cholinergic nerve fibers. Standard formaldehyde treatment showed endocrine-like cells with cytoplasmic granules arranged in a single layer around the gastric lumen, and some eterochromaffin cells. After exposure to HCl, the endocrine-like cells were strongly fluorescent, and the fluorescence of the enterochromaffin cells and adrenergic nerve fibers was strongly reduced or abolished. These findings suggest the direct involvement of cholinergic innervation in the secretion of pepsin and HCl acid. It is further concluded that gastrin release is controlled by the cholinergic nerve fibers innervating gastrin-containing cells.

6738 EVIDENCE OF NONVAGAL NEURAL STIMULATION OF CANINE GASTRIC ACID SECRETION. *(E.)*

Tansy, M. F.; Probst, S. J.; Martin, J. S. (Temple Univ. Health Sciences Center, Philadelphia, Pa.). *Surg. Gynecol. Obstet.* 140(6):861-867, 1975.

Gastric secretory responses to central vagal stimulation were studied in male and female mongrel dogs during suppression of alpha-adrenergic effects. A cannula was inserted into the common bile duct of the fasted dogs for external diversion of the bile and a Thomas cannula was placed into the corpus of the stomach for collection of the gastric juice. Gastric acid secretion in response to electrical stimulation of the vagosympathetic trunks was studied before and after the i.v. administration of phenoxygenzamine hydrochloride, atropine sulfate, and burimamide hydrochloride. The response was also tested following surgical interruption of the splanchnic nerves and direct electrical stimulation of the peripheral ends of these nerves. Central vagal stimulation subsequent to alpha-adrenergic blockade was associated with marked elevations in the total volume of gastric secretion and in acidity. The response was not blocked by a subsequent large dose of atropine. Acid secretion was never obtained from the gastric mucosa on phenoxybenzamine hydrochloride stimulation. The reflex increase in gastric acid secretion during alpha-adrenergic blockade was abolished by surgical interruption of the splanchnic nerves and reinstituted by direct stimulation of these nerves. The latter response was not completely blocked by atropine but was abolished by burimamide. Burimamide also abolished the elevated acid secretory response produced by multiple central stimulation of both vagi during alpha-adrenergic blockade. It is concluded that a heretofore unsuspected second neural pathway exists in the dog which is capable of influencing gastric acid secretion.

6739 EFFECT OF CONTINUOUS INFUSION OF PENTAGASTRIN ON LOWER ESOPHAGEAL SPHINCTER PRESSURE AND GASTRIC ACID SECRETION IN NORMAL SUBJECTS. *(E.)*

Walker, C. O.; Frank, S. A.; Manton, J.; Fordtran, J. S. (Dallas Veterans Admin. Hosp., Dallas, Tex. 75216). *J. Clin. Invest.* 56(1):218-225, 1975.

The effect of a continous 1-hr infusion of pentagastrin on lower esophageal sphincter (LES) pressure was studied, and was correlated with the acid secretory response by stomach parietal cells. In the first period of study, isotonic saline was infused i.v. for 30 min (control). Pentagastrin was then infused i.v. for 1 hr. The third period was begun by replacing the pentagastrin infusion with saline for 40 min. The effects of different doses of pentagastrin were measured in different groups of from eight to 13 normal subjects (group dose-response studies); two subjects had a complete dose-response examination (four or five studies at each of seven doses; individual dose-response studies). Results of the group dose-response studies showed that gastric acid secretion was significantly stimulated by infusion of 0.025 μg/kg/hr and higher doses of pentagastrin. There was no significant elevation in LES pressure during 1-hr infusion of pentagastrin (0.004-12 μg/kg/hr). An i.v. bolus injection of pentagastrin (0.5 μg/kg/hr) together with 0.9 and 1.5 μg/kg/hr pentagastrin infusion significantly increased LES pressure. The results of the individual dose-response studies showed that in the first subject, LES pressure was increased from 37 to 50 mm of Hg with the 0.9 μg/kg/hr infusion of pentagastrin alone. The same infusion rate in the other subject increased LES pressure from 38 to 49 mm of Hg. In both these subjects, this dose of pentagastrin elicited secretion rates of gastric acid equal to those induced by a 12 μg/kg/hr infusion. The calculated half-maximal dose for acid secretion was 0.15 μg/kg/hr for the first subject and 0.35 μg/μg/hr for the second subject. There was no significant correlation between acid secretion rate and LES pressure. These results are in contrast to previous findings and suggest that serum gastrin may not be the major determinant of LES pressure.

6740 PLASMA SHEDDING BY THE CANINE OXYNTIC AND PYLORIC GLANDULAR MUCOSA INDUCED BY TOPICAL ACTION OF ACETYLCHOLINE: EFFECT OF ATROPINE AND PHYSOSTIGMINE. *(E.)*

Davenport, H. W.; Kauffman, G. L., Jr. (Dept. Physiology, Univ. Michigan, Ann Arbor, Mich.). *Gastroenterology* 69(1):190-197, 1975.

The effects of various drugs on the acetylcholine-induced shedding of plasma proteins by the oxyntic glandular mucosa were studied in dogs with Heidenhain pouches or vagally denervated antral pouches. The fasted animals were injected i.v. with Evans blue (25 mg) and 40 ml of buffer was placed in the Heidenhain pouch or 20 ml was placed in the antral pouch. After 30 min, the volume of fluid in the pouch was measured and the fluid was analyzed for the presence of dye. This procedure was repeated following the placement of 20 or 40 ml of acetylcholine bromide in the pouch. The effects of topical and/or i.v. atropine sulfate, gallamine triethiodide, physostigmine, d-tubocurarine, and succinylcholine were also studied. Irrigation of the Heidenhain and antral pouches with acetylcholine caused the mucosa to shed plasma protein and caused the potential differences across the mucosa to fall. The response was dose-related, with the minimum effective concentration of acetylcholine bromide ranging from 0.1 to 1.0 g/100 ml. Topical atropine (50 mg/100 ml) completely blocked the effects of acetylcholine on plasma shedding and potential difference, a similar effect being produced by i.v. atropine (0.2 mg/kg). The minimal effective dose of atropine varied between 0.005 and 0.0125 mg/kg. The effect of low concentrations of acetylcholine was enhanced by concurrent irrigation with physostigmine (minimal effective dose, 0.3 mg/100 ml), but was not affected by concurrent irrigation (0.5 g/100 ml) with or i.v. (5 mg/kg) hexamethonium chloride. Similarly, the effects of acetylcholine on plasma shedding were not prevented by topical gallamine triethiodide (0.5 g/100 ml) or *d*-tubocurarine (0.15 g/100 ml). Topical succinylcholine chloride (1 g/100 ml) did not cause plasma shedding or a fall in potential difference. The data suggest that although high concentrations of acetylcholine are needed to cause plasma shedding, only a small amount of the applied acetylcholine acts at some relatively inaccessible site.

6741 FAILURE OF CHOLESTRYAMINE TO PREVENT BILE SALT INJURY TO MOUSE GASTRIC MUCOSA. *(E.)*

Eastwood, G. L. (U.S. Naval Hosp., Philadelphia, Pa.). *Gastroenterology* 68(6):1466-1472, 1975.

The effects of cholestryamine on bile salt-induced injury to the mouse gastric mucosa were studied. Solutions of taurocholate or glycochenodeoxycholate, with or without added cholestyramine resin (9 mg/ml), were instilled into the stomachs of fasted mice at pH 1, 3, 5, or 7. Sections of the greater curvature were subsequently examined by light microscopy and graded as normal, mildly injured (spotty changes in the cellular staining characteristics of some surface epithelial cells), moderately injured (more generalized changes and/or disruption of the surface epithelium in several places), or severely injured (extensive mucosal destruction). Cholestyramine alone caused mild injury at pH 1, but produced no detectable injury at pH 7. At pH 1, all mice receiving 0.1 or 2 mM taurocholate, with or without cholestyramine, had gastric mucosal damage. At pH 3, 5, and 7, taurocholate produced no changes. Glycochendeoxycholate caused injury at pH 1 and 3, the damage being slightly but insignificantly reduced by cholestyramine. The *in vitro* binding of 2 mM taurocholate by cholestyramine (4 mg/ml) was nearly complete at pH 3, 5, and 7, and at 20 mg/ml, cholestyramine was able to bind 89% of the bile salt at pH 1. The results suggest that for cholestyramine to be effective in binding the bile salts in the treatment of gastric ulcer, cholestyramine would have to be administered in greater quantity than the usual 4 g three times/day and/or the pH of the stomach would have to be maintained above 4-5 by the frequent administration of antacids.

6742 THE EFFECT OF VITAMIN A ON GASTRIC MUCUS AND STRESS ULCERATION IN THE RESTRAINED RAT. *(E.)* Wilson, S. E.; Hiatt, J. R.; Davis, R. S. (Veterans Admin. Wadsworth Hosp. Center, Los Angeles, Calif.). *Surg. Italy* 4(1):35-40, 1974.

Mucus production and the effects of vitamin A on mucus production and stress ulceration were studied in normal and restraint-stressed Wistar rats. In the first experiment, 120 rats were restrained for 12, 18, or 24 hr, with one-half of the rats serving as controls and the rest injected s.c. with aqueous vitamin A (5000 U) immediately prior to restraint. In the second experiment, 59 rats were fasted for 24 hr (controls) or restrained for 24 hr, and/or injected s.c. with aqueous vitamin A (5000 U). After both studies, the animals' stomachs were opened along the greater curvature and checked for evidence of ulceration; after the second study, the gastric mucosa was also analyzed for hexosamine, a primary constituent of mucus. In the first experiment, the ulcerative index in all animals increased with the duration of stress. In the animals pretreated with vitamin A, the number of ulcers was significantly lower after each period of stress restraint, particularly after 24 hr of restraint. In the second experiment, the average hexosamine content in the control mucosa was 0.56 mg/0.1 g while in untreated stressed rats, this value was significantly reduced to 0.36 mg/0.1 g. The mucosal hexosamine content in stressed rats pretreated with vitamin A did not differ significantly from that of the untreated stressed rats. Vitamin A did not significantly increase mucus levels in either the stressed or unstressed rats. It is concluded that vitamin A reduces the severity of acute mucosal ulceration in the stressed rat, that the hexosamine content of the superficial gastric mucosal layer is decreased with stress ulceration, and that vitamin A does not appear to significantly increase mucus production in stress ulceration.

6743 GASTRIC ACID SECRETION AND SLEEP STAGES DURING NATURAL NIGHT SLEEP. *(E.)* Stacher, G.; Presslich, B.; Starker, H. (1 Chir. Univ. Klinik, Alserstr 4, A-1097, Wien, Austria). *Gastroenterology* 68(6):1449-1455, 1975.

The relation between wakefulness and the different stages of natural night sleep and gastric acid secretion was studied in four healthy female volunteers for 11 nights. Measurement of gastric acid secretion was carried out by means of the intragastric titration technique and a telemetering capsule swallowed at the commencement of each experiment. Electroencephalogram recordings and eye movements were continuously monitored by monopolar scalp and bipolar facial leads. Acid output was determined prior to the onset of sleep, after awakening, during arousals and longer periods of wakefulness in the course of the night, and during the different stages of sleep. Compared with the waking state, sleep was associated with significantly reduced levels of acid secretion. Although there were no significant differences between acid secretion during sleep stages 1-4 and rapid eye movement (REM) sleep, acid secretion decreased in the deeper stages of sleep. During all REM phases, only small amounts of acid were produced. Arousal or periods of waking in the course of the night, as well as waking in the morning, were associated with significant increases in acid output. The high rate of secretion was maintained during the whole period after wakening, as long as the subject did not fall asleep again. Similar studies should be performed in duodenal ulcer patients.

6744 PYLORIC REFLUX GASTRITIS: THE OFFENDING AGENT. *(E.)* Delaney, J. P.; Broadie, T. A.; Robbins, P. L. (Univ. Minnesota Health Sciences Center, 412 S.E. Union St., Minneapolis 55455). *Surgery* 77(6):764-772, 1975.

The abilities of bile, pancreatic juice, and whole intestinal contents to induce morphologic changes in the canine gastric mucosa were compared. Full-thickness tubes were fashioned from the greater curvature of the canine stomach, pedicled on the short gastric vessels, and interposed in the upper jejunum of 12 dogs. In a second group of dogs, the segment of duodenum bearing the main pancreatic duct was anastomosed to the gastric tube, thereby exposing the stomach corpus mucosa to essentially pure pancreatic juice. In the third group of animals, bile was diverted over the gastric mucosa by ligating the common bile duct and anastomosing the gallbladder to the gastric tube. Biopsies of the tube and parent stomach were obtained at initial surgery and four months to two yr later; the specimens were compared with respect to parietal cell number, mucus cell number, inflammation, glandular disorder, and surface-cell hyperplasia. Exposure of the stomach mucosa to whole intestinal contents resulted in a 56% reduction in parietal cell density compared with a normal control group, while exposure to pancreatic juice resulted in a 49% reduction and exposure to bile in a 32% reduction. The degree of inflammation and mucus cell hyperplasia was also greater in mucosa exposed to intestinal juice than in mucosa exposed to pancreatic juice or bile; all three groups differed significantly from the controls. The overall gastritis scores did not differ significantly between the bile and pancreatic juice groups, but that of the intestinal juice group was significantly greater than those of the other two groups. The experimental gastric mucosa also differed from the control mucosa in the appearance of cysts in the deep glands of the mucosa, a disorderly appearance to the mucosa, and a reduction in chief cells; the experimental and control mucosa did not differ in mucosal thickness. The changes in the experimental mucosa did not progress with time. The data suggest that gastritis may result from long-term exposure to a mixture of enzymes, detergent substances, and endogenous acid.

6745 INCREASED PLASMA GASTRIN LEVELS IN CONNECTION WITH INHIBITION OF GASTRIC ACID RESPONSES TO SHAM FEEDING FOLLOWING BULBAR PERFUSION WITH ACID IN DOGS. *(E.)* Nilsson, G. (Dept. Pharmacology, Karolinska Institutet, S-104 01 Stockholm 60, Sweden). *Scand. J. Gastroenterol.* 10(3):273-277, 1975.

The effect of bulbar acidification on plasma gastrin and gastric acid responses to sham feeding was studied in two mongrel dogs with esophageal fistulas, gastric cannula, and mucosal septal pouches of the fundic stomach (Pavlov type) and duodenal bulb. Gastric secretion from the Pavlov pouches was determined during a basal period and after stimulation by sham feeding of minced cooked beef in water; the volume was measured and the acidity determined by titration with 0.01 N NaOH. Perfusion of the bulbar pouches with 0.9% NaCl or 0.1 N HCl was performed throughout the experiment and pH determinations of the effluent perfusates were performed at 15-min intervals. Gastrin concentrations in blood samples taken every 15 min were measured by radioimmunoassay. The gastrin-like immunoreactivity measured in this way behaved like the porcine gastrin standard. Cross-reactivity with cholecystokinin-pancreozymin, the only natural peptide known to significantly cross-react with antigastrin antisera, was negligible. Perfusion of the bulbar pouches with 0.1 N HCl profoundly inhibited the acid output from the Pavlov pouches in response to sham feeding, the acid responses from the gastric fistulas being similarly inhibited. Sham feeding increased plasma gastrin concentrations in both the control and inhibitory experiments, but these concentrations were much higher in the inhibitory experiments than in the control. The data support the hypothesis that the bulbar mechanism inhibits acid secretion by interfering with the stimulatory action of gastrin at the HCl-producing glands.

6746 EFFECT OF ACID IN THE DUODENAL BULB ON ACID AND PEPSIN RESPONSES TO TEST MEAL IN DOGS. *(E.)* Nilsson, G. (Dept. Pharmacology, Karolinska Institutet, S-104 01 Stockholm 60, Sweden). *Scand J. Gastroenterol.* 10(3):279-282, 1975.

The effect of acid in the duodenal bulb on gastric acid and pepsin secretion was studied in five dogs with innervated pouches of the fundic stomach (Pavlov type) and the duodenal bulb. Gastric acid and pepsin output and pepsin concentration in gastric juice were determined under basal conditions. The dogs were then fed a cooked beef liver meal and in some cases the bulbar pouches were perfused with 0.1 N HCl (80 ml/hr). The volume of gastric juice, pH of the effluent perfusate, and pepsin concentration were determined in 15-min samples collected over the following three hr. Bulbar perfusion with acid profoundly inhibited the secretion of acid from the gastric pouches, the average reduction being 68% of basal secretion. The total output of pepsin was also reduced to 41% of basal levels during bulbar acidification; in addition, the pepsin concentration in the gastric juice was generally lower during bulbar perfusion with acid. The data suggest that secretin is not the humoral agent response for the inhibition of acid secretion during bulbar acidification.

6747 EFFECT OF BULBAR PERFUSION WITH ACID, HYPERTONIC SOLUTIONS, AND ACETYLCHOLINE ON GASTRIC ACID SECRETION IN DOGS. *(E.)* Nilsson, G. (Dept. Pharmacology, Karolinska Institut, S-104 01 Stockholm 60, Sweden). *Scand. J. Gastroenterol.* 10(3):283-287, 1975.

The effects of bulbar perfusion with 0.1 N HCl, hypertonic solutions of 40% glucose, 40% peptone, or 40% NaCl, and 0.1% acetylcholine chloride on gastric acid secretion were studied in three mongrel dogs with Pavlov pouches of the fundic stomach and proximal portion of the duodenum; one dog was also provided with an isolated pouch of the distal duodenum. Beginning two hr before the bulbar perfusions, pentagastrin (40 μg/hr) in 0.9% saline was given as a continuous i.v. infusion for five hr. The gastric acid secretions were collected in 15-min samples. Bulbar perfusion with 0.1 N HCl profoundly inhibited acid secretion from the Pavlov pouches, while perfusion with glucose, NaCl, or peptone solutions had no significant influence on the average acid output. Perfusion with acetylcholine produced a transient inhibition of gastric secretion, the degree of inhibition varying from dog to dog. Perfusion of the distal duodenal segment in one dog with glucose did not significantly influence the gastric acid output. It is concluded that hypertonic solutions are not activators of the bulbar inhibitory mechanism which responds to reductions in the intrabulbar pH. Inhibition following bulbar perfusion with acetylcholine may indicate that the liberation of a hypothetical humoral agent, bulbogastrone, is to some extent under cholinergic control.

6748 IN VIVO STUDIES ON THE NEUTRALIZING EFFECT OF ANTACIDS USING THE HEIDELBERG CAPSULE. *(E.)* Ekenved, G.; Walan, A. (Res. Lab., AB Hassle, Molndal, Sweden). *Scand. J. Gastroenterol.* 10(3):267-272, 1975.

The effects of various antacid preparations on gastric pH were studied in six healthy volunteers, aged 23-43 yr. The intragastric pH was measured by the Heidelberg radiotelemetry capsule method and the aspiration technique. The *in vitro* rate of reaction between human gastric juice and the four antacid preparations [a liquid preparation, a chewable tablet (tablet A), and 2 tablets (tablets B and C) designed to be swallowed whole] was assayed by titration at constant pH. The preparations were given to fasting subjects in a dosage corresponding to a neutralizing capacity of 50-60 mEq HCl. At low pH levels (less than 2), the Heidelberg capsules recorded lower values than were obtained with the aspiration technique, but when the pH response to an antacid dose was studied the two techniques give concordant results. The liquid antacid preparation and tablet A give almost equivalent results, with a short latency period and a duration of action of more than one hr (mean 69 min and 82 min, resp.). Tablets B and C gave less prompt effects with a shorter duration of action (mean 45 min for both). The clinical interpretation of these results should be limited to situations involving an empty stomach.

6749 EFFECT OF URIDINE DIPHOSPHO-N-ACETYLGLUCOSAMINE AND SODIUM SALICYLATE ON L-GLUTAMINE-D-FRUCTOSE-6-PHOSPHATE AMINOTRANSFERASE ACTIVITY FROM RAT GASTRIC MUCOSA.

(E.) Chan, J.; Lee, K. H. (Sch. Pharmacy, Univ. California, San Francisco 94143). *J. Pharm. Sci.* 64(7):1182-1185, 1975.

The mechanisms of action of sodium salicylate and uridine-5'-diphospho-*N*-acetylglucosamine on L-glutamine-D-fructose-6-phosphate aminotransferase prepared from Sprague-Dawley rat gastric mucosa were studied, as were interactions between the two inhibitors. The effect of these two inhibitors on enzyme activity was determined by the rate of glucosamine formation in mucosal supernatant protein fractions during incubation in the presence of L-glutamine and glucose-6-phosphate. At 10-20 mM, sodium salicylate reversibly inhibited aminotransferase activity by competing with glucose-6-phosphate. At higher concentrations, salicylate inactivated the enzyme irreversibly, with an inactivation rate following first order kinetics with response to enzyme concentration. Uridine-5'-diphospho-*N*-acetylglucosamine, an endogenous feedback inhibitor, also inhibited the aminotransferase-catalyzed reaction by competing with glucose-6-phosphate; its inhibiting activity was 1000 times that of salicylate. Uridine-5'-diphospho-*N*-acetylglucosamine reduced the salicylate inhibition of the enzymic reaction and protected the enzyme from salicylate-induced irreversible inactivation. At a fixed concentration of uridine-5'-diphospho-*N*-acetylglucosamine (7×10^{-6} M), increasing concentrations of salicylate produced an increase in enzyme activity as compared with the control. Fructose-6-phosphate at 10^{-2} M also protected the enzyme against inactivation by 40 mM salicylate, while glutamine offered no such protection. The data suggest that sodium salicylate and uridine-5'-diphospho-*N*-acetylglucosamine apparently bind to the same site on the enzyme.

6750 ELECTROPHYSIOLOGICAL EFFECTS OF BURIMAMIDE AND 16,16-DIMETHYL PROSTAGLANDIN E_2 ON THE CANINE GASTRIC MUCOSA.

(E.) Bowen, J. C.; Kuo, Y. J.; Pawlik, W.; Williams, D.; Shanbour, L. L.; Jacobson, E. D. (Univ. Texas Medical Sch., 6400 W. Cullen, Houston 77025). *Gastroenterology* 68(6):1480-1484, 1975.

The electrophysiological effects of two potent inhibitors of gastric acid secretion, burimamide and 16,16-dimethyl prostaglandin E_2 (dm-PGE$_2$), were determined in an *in vivo* histamine-stimulated canine stomach preparation and an *in vitro* canine gastric mucosal preparation. In the *in vivo* preparations, a flap of stomach from the oxyntic gland area was secured within a partitioned chamber bathed with isotonic saline. Submaximal acid secretion was produced by i.v. histamine infusion (1.5 μg/kg-min). The transmural potential difference (PD) across the stomach preparation was determined before and after i.v. injection of a burimamide bolus (8.28 mg) or i.v. infusion of dm-PGE$_2$ (0.005 μg/kg-min for 1 hr). In the *in vitro* preparations, paired segments of gastric mucosa were mounted in identical flux chambers. Unidirectional fluxes of labeled sodium and chloride were determined before and after the addition of burimamide (3×10^{-4}M) or dm-PGE$_2$ (0.02 or 0.2 μg/ml) to the bathing solution on the serosal surface. In the *in vivo* preparation, burimamide caused a decrease in acid secretion, an increase in PD, and no significant change in the relative resistance (R). Dm-PGE$_2$ also inhibited acid secretion and increased the PD, but it also increased R. In the *in vitro* preparation, the unidirection flux of sodium from mucosa to serosa increased after dm-PGE$_2$ but not after burimamide. The passive sodium fluxes and unidirectional chloride fluxes were not altered after either agent. The data suggest that increased active transport of sodium from mucosa to serosa is at least partially responsible for the observed increase in transmural PD after dm-PGE$_2$, an agent which also decreases H$^+$ transport. With burimamide, the increased PD was due primarily to the inhibition of H$^+$ secretion.

6751 EFFECT OF CALCITONIN ON SERUM GASTRIN CONCENTRATION AND COMPONENT PATTERN IN MAN.

(E.) Frahrenkrug, J.; Hornum, I.; Rehfeld, J. F. (Bispebjerg Hosp., Copenhagen, Denmark). *J. Clin. Endocrinol. Metab.* 41(1):149-152, 1975.

The effects of synthetic salmon calcitonin on serum concentrations and distribution of the four main forms of gastrin and on serum concentrations of total and ultrafiltrable calcium were studied in nine normal subjects and three patients with pernicious anemia. In the normal subjects, the mean basal serum gastrin concentration was 26 pM/liter, as measured radioimmunochemically. Administration of calcitonin (0.7 Medical Research Council U/kg, i.v.) resulted in a significant decrease in serum gastrin levels measured at 20, 45, 60, and 90 min postinjection. Calcitonin given at the beginning of a protein-rich meal lowered the gastrin response significantly at 5-30 min after injection. In the three patients with pernicious anemia, serum gastrin concentrations were 1286 pM/liter before and 628 pM/liter after calcitonin injection. Sephadex gel filtration of sera from the three patients revealed that while calcitonin lowered the concentrations of all four main gastrin components, the decrease was most pronounced for the small components III and IV (gastrin-17 and gastrin-13). Calcitonin produced no significant changes in serum calcium concentrations or in unfilterable calcium concentrations calculated from calcium and albumin concentrations. No side effects were noted. The data suggest that calcitonin acts directly on the gastrin cells in the gastric antrum and duodenum.

6752 EFFECT OF CARBACHOLINE AND URECHOLINE ON PENTAGASTRIN-STIMULATED GASTRIC SECRETION IN HEALTHY SUBJECTS.

(E.) Roland, M.; Berstad, A.; Liavag, I. (Aker Univ. Hosp., Oslo 5, Norway). *Scand. J. Gastroenterol.* 10(4):357-362, 1975.

The effect of two cholinomimetics, carbacholine and urecholine, on the gastric mucosa were studied. Pentagastrin (0.15, 1.5 and 15 μg/kg/hr) either alone or in combination with carbocholine (2 μg/kg/hr) or urecholine (60 μg/kg/hr) was administered i.v. in each of six healthy subjects. Tests were performed in random order on different days. Each of eight 15-min samples (one basal and seven postinfusion) was analyzed for volume, pH, H$^+$, and pepsin. After pentagastrin alone there was a significant increase in acid output with 0.15 to 1.5 μg/kg/hr, but no further increase with 15 μg/kg/hr. At all pentagastrin doses, acid output was higher after pentagastrin plus urecholine than after pentagastrin plus carbacholine, but the differences were not significant. With 0.15 μg/kg/hr pentagastrin alone, pepsin output was lower than with both of the combined infusions, but only the difference between pentagastrin plus urecholine and pentagastrin alone was significant. After pentagastrin alone there was a significant increase in gastric juice volume from the lowest to the middle dose and a slight inhibition after the third dose. When carbacholine or urecholine was added to pentagastrin, the volume of gastric juice increased significantly from the lowest to the highest dose. At all dose steps of pentagastrin, the volume of gastric juice was higher after infusion of urecholine than of carbacholine, and at the two lowest doses the differences were significant. The volume of gastric juice was also higher after pentagastrin plus urecholine than after pentagastrin alone, and the differences were significant at the lowest and the highest doses. It is suggested that the cholinimimetics increased the sensitivity of the parietal cells to pentagastrin stimulation.

6753 EFFECTS OF CYCLIC ADENOSINE 3':5'-MONOPHOSPHATE AND RELATED AGENTS ON ACID SECRETION BY ISOLATED RABBIT GASTRIC MUCOSA.

(E.) Fromm, D.; Schwartz, J. H.; Quijano, R. (Harvard Medical Sch., Boston, Mass.). *Gastroenterology* 69(2):453-462, 1975.

The effects of various adenosine phosphate compounds, theophylline, histamine, and metiamide on steady states of acid secretion by isolated New Zealand rabbit fundic mucosa were studied. The tissue was mounted on a Lucite half-chamber and perfused with Ringer's solution. Steady-state rates of luminal acid secretion were measured by the pH stat method and the transmural electrical potential difference (PD) and short-circuit current (Isc) were also measured. The steady acid secretory and PD responses to dibutyryl AMP (DB-AMP), cyclic AMP, 2':3'-AMP, 5'-AMP, ATP, histamine, theophylline, and/or metiamide added to the serosal bathing solution were then determined. Cyclic AMP (5 mM or greater), DB-AMP (more than 0.45 mM), histamine (0.05 mM or greater) and theophylline (greater than 3 mM) increased the rate of acid secretion, and the addition of theophylline in a concentration which had no stimulatory effect (less than 3 mM) reduced the effective concentrations of cyclic AMP or histamine required for stimulation of acid secretion. Measurements of lactate, pyruvate, and CO$_2$ indicated that the increases in acid secretory rats were predominantly due to H$^+$ and not to the accumulation of organic acid in the luminal bathing solution. ATP (0.75 mM) and 5'-AMP (4 mM), but not 2':3'-AMP (10 mM), also stimulated acid secretion. Metiamide (3 mM) prevented the stimulatory effects of histamine and ATP, but it did not prevent the stimulatory effects of DB-AMP, theophylline, or 5'-AMP. The data suggest that cyclic AMP is involved in the regulation of acid secretion by the rabbit stomach and are consistent with the hypothesis that histamine and ATP require adenylate cyclase activity for stimulation of acid secretion and 5'-AMP inhibiting phosphodiesterase activity.

6754 EFFECTS OF DRUGS INFLUENCING GASTRIC SECRETION ON THE QUANTITATIVE HISTOLOGICAL DISTRIBUTION OF CYCLIC ADENOSINE 3':5'-MONOPHOSPHATE IN THE RAT STOMACH.

(E.) Katsumata, Y.; Glick, D. (Stanford Res. Inst., Menlo Park, Calif.). *Gastroenterology* 69(2):409-415, 1975.

Studies were undertaken to clarify the role of cyclic AMP in acid secretion in the rat stomach and to quantitate the effects of gastric stimulatory and inhibitory drugs on the cyclic AMP concentrations within the glandular stomach. Sixty min before sacrifice, fasted (24 hr) male Sprague-Dawley rats were injected s.c. with the secretion-stimulating drugs pentagastrin (250 μg/kg), urecholine (100 μg/kg), or histamine (2 or 40 mg/kg), or with the inhibitors atropine sulfate (2 mg/kg) or prostaglandin E$_2$ (PGE$_2$, 1 mg/kg). In some experiments, these drugs were combined with theophylline (200 mg/kg, i.p., 15 min before sacrifice), a drug that prevents enzymatic degradation of cyclic AMP. Controls received s.c. or i.p. injections of 0.9% NaCl, the solution in which the test compounds were administered. Cyclic AMP concentrations in circular fresh-frozen microtome sections, representing the various histologic regions of the glandular stomach, were measured by the firefly luminescence method. The peak cyclic AMP concentrations in the NaCl-injected controls were found in the parietal-mucous neck cell region (3.3 pM/mg wet weight; 0.11 pM/μg protein-nitrogen). Pentagastrin and urecholine alone increased the peak values slightly (both about 4 pM/mg wet weight; 0.15 pM/μg protein-nitrogen). Theophylline alone had a slightly greater effect (5.4, 0.22), but theophylline given with pentagastrin or urecholine greatly elevated the values (8.3, 0.31). In addition, urecholine or pentagastrin plus theophylline generated two approximately equal cyclic AMP concentration peaks (about one-half the parietal-mucous neck cell peak value) in the chief cell and muscle regions. Histamine at 40 mg/kg slightly suppressed the parietal-mucous neck cell concentrations (2.7, 0.11), but at 2 mg/kg, it elevated these values significantly; histamine (2 mg/kg) plus theophylline had an even greater effect (9.1, 0.32). The other histological regions were not significantly influenced by histamine. Neither atropine nor PGE$_2$, alone or in combination with theophylline, had much influence on the parietal-mucous neck cell cyclic AMP levels; but both caused significant increases in the chief cell and muscle levels. The data indicate a cyclic AMP involvement in the stimulation of acid secretion in the rat stomach.

6755 CYCLIC NUCLEOTIDE REGULATION OF GASTRIC ACID SECRETION.

(E.) Charters, A. C.; Chandler, J. G.; Flamant, Y. M.; Faulkner, M. A.; Orloff, M. J. (Univ. California, San Diego Sch. Medicine, La Jolla). *Surg. Forum* 24:361-363, 1973.

Intracellular cyclic AMP concentrations and adenyl cyclase and phosphodiesterase activities were measured in the frog isolated gastric mucosa in the basal state and during pentagastrin-stimulated acid secretion. The gastric mucosa from *Rana pipiens* were mounted on plastic syringe barrels and immersed in a nutrient serosal solution; unbuffered mucosal solution was added to the syringe barrel. Acid secretion was measured before and after the addition of pentagastrin (10^{-6} M) to the serosal solution. Cyclic AMP levels were examined at the midportion of the secretory response curve for pentagastrin, and adenyl cyclase and phosphodiesterase activities were estimated from the cyclic AMP levels. Pentagastrin elicited a mean 74% increase over basal acid secretion. In the stimulated, but not the control, mucosa, the intracellular cyclic AMP concentration correlated significantly with the acid secretory response. Adenyl cyclase activity and the cyclic AMP concentration were significantly related in both the unstimulated and control mucosa; phosphodiesterase activity did not correlate with cyclic AMP levels and there was no apparent relation between acid secretion and phosphodiesterase activity. The data support the hypothesis that the adenyl cyclase-cyclic AMP system is the intracellular mediator of pentagastrin-stimulated acid secretion.

6756 CYCLIC GMP IN STIMULATED GASTRIC MUCOSA.

(E.) Eichhorn, J. H.; Salzman, E. W.; Silen, W. (Harvard Medical Sch., Boston, Mass.). *Surg. Forum* 24:363-365, 1973.

The effects of cholinergic stimuli on the gastric mucosal levels of cyclic guanosine 3'5'-monophosphate (cGMP) were studied using strips of fundic gastric mucosa from adult mongrel dogs. Prior to removal of the mucosal strips, the dogs were subjected to: electrical stimulation of the distal transected vagus trunks above the diaphragm; infusion of acetylcholine (ACh, 0.05 mg/min) into the celiac artery; pretreatment with atropine (1.0 mg/5 kg) before electrical stimulation of the vagi; or i.v. pentagastrin infusion (10 μg/kg/hr). The mucosal strips were acid extracted and fractionated on a formate ion-exchange resin column. The cGMP-containing fraction was assayed by a double radioimmune method. Electrical stimulation of the vagus nerves produced a marked increase in the cGMP content of the fundic mucosa, an effect which was blocked by pretreatment with atropine. ACh infusion also produced significant increases in the cGMP concentration, but pentagastrin had no such effect. The data demonstrate an *in vivo* association between cholinergic stimuli and an increase in gastric mucosal cGMP. Combined with previous results, they suggest that cGMP may serve as a mediator of cholinergic stimuli, analogous to the postulated "second messenger" role of cAMP for adrenergic stimuli.

6757 EFFECT OF DIAZEPAM ON UNSTIMULATED AND ON STIMULATED GASTRIC SECRETION.

(E.) Bennett, P. N.; Davies, P.; Frigo, G. M.; Weerasinghe, M. T.; Lennard-Jones, J. E. (Univ. Coll. Hosp., London, England). *Gut* 15(11):101-103, 1974.

The effect of i.v. diazepam on unstimulated and pentagastrin-stimulated gastric secretion was studied in 12 normal male and female subjects. Gastric secretion was collected by suction pump through a nasogastric tube placed in the fasted subjects. Pentagastrin (6 μg/kg/hr) was infused for 2.25 hr. Serial collections of gastric juice were made at 15-min intervals in the unstimulated and pentagastrin-stimulated subjects, then were repeated in both groups during the i.v. administration of diazepam (0.14 mg/kg). The volume of secretion was reduced in all six unstimulated subjects following diazepam, and in five subjects the acid content was reduced. However, diazepam had no significant effect on the volume of secretion or acid content in the pentagastrin-stimulated subjects. The results indicate that diazepam may reduce nonstimulated gastric secretion by a centrally mediated action; this effect may be of advantage in peptic ulcer therapy.

6758 RELEASE OF IMMUNOREACTIVE GASTRIC INHIBITORY POLYPEPTIDE (IR-GIP) BY ORAL INGESTION OF FOOD SUBSTANCES.

(E.) Cleator, I. G. M.; Gourlay, R. H. (Dept. Surgery Physiology, Univ. British Columbia, Vancouver, B. C., Canada). *Am. J. Surg.* 130(2):128-135, 1975.

The purpose of this study was to examine the pattern of immunoreactive gastric inhibitory polypeptide (IR-GIP) release in man after oral ingestion of various food substances in an attempt to find a specific releaser of IR-GIP for use in further studies of the role of GIP in physiologic and pathologic conditions. All studies were performed in adult subjects after an overnight fast. The subjects had no history of gastrointestinal diseases and no family history of diabetes, and they were within 10% of ideal body weight. Each study was carried out in at least six subjects, except an i.v. porcine GIP infusion study, in which three subjects had two tests each. The mean fasting IR-GIP level in 107 normal subjects was 410 ± 23 pg/ml. Lipomul (an oleic acid suspension), glucose (Pal-a-dex 100), galactose, and leucine, all given p.o., significantly elevated the serum IR-GIP level in man. Inhibition of acid and pepsin secretion (enterogastrone effect) was demonstrated after elevation of serum IR-GIP levels by introduodenal administration of Lipomul and by i.v. infusion of porcine IR-GIP. Increases in serum IR-GIP levels induced by p.o. glucose or i.v. porcine GIP were associated with increases in serum immunoreactive insulin levels. I.v. glucose had no effect on the serum IR-GIP level but produced an increase in the immunoreactive insulin level. Concurrent administration of Lipomul and i.v. glucose induced a significant decrease in the serum IR-GIP level. It is postulated that GIP releases insulin and that insulin, in turn, inhibits GIP release.

6759 THE INTESTINAL PHASE OF GASTRIC SECRETION: A PHARMACOLOGICAL PROFILE OF ENTERO-OXYNTIN.

(E.) Way, L. W.; Cairns, D. W.; Deveney, C. W. (Dept. Surgery, Univ. California, San Francisco 94121). *Surgery* 77(6):841-850, 1975.

The pharmacologic properties of entero-oxyntin, the hormone responsible for the intestinal phase of gastric secretion, were studied in male and female mongrel dogs prepared with antrectomies, gastrojejunostomies, and Heidenhain pouches. A Gregory cannula was placed in the Heidenhain pouch and a Thomas cannula was placed in the gastric remnant as a gastric fistula. The dogs were fed a meal of cooked liver with 5% bone meal and the gastric acid was collected in continuous 15-min samples. In subsequent experiments, the dogs were given i.v. histamine dihydrochloride (0.10 mg/kg/hr for 3.5 hr), i.v. pentagastrin (8 μg/kg/hr for 3.25 hr), the octapeptide of cholecystokinin (OP-CCK, 400 ng/kg/hr for 2.5 hr i.v.), i.v. cholecystokinin (4 U/kg/hr for 1 hr), s.c. bethanecol (0.1 mg/kg/hr for 3 hr), i.v. secretin (2 U/kg/hr for 1 hr), i.v. atropine (0.06 mg/kg bolus), and i.v. metiamide (3 μM/kg bolus) during the period of maximal feeding-stimulated acid secretion. Acid secretion from the Heidenhain pouch was stimulated by feeding with no increase in the serum gastrin concentrations. Simultaneous administration of pentagastrin, histamine, OP-CCK, or bethanecol potentiated the acid secretion, while atropine and metiamide inhibited secretion; secretin and glucagon were without significant effect. The results suggest that entero-oxyntin differs from antral gastrin, histamine, and cholecystokinin-pancreozymin, and that it activates a separate set of receptors on the parietal cells. Secretagogue potentiation may normally be important in determining the acid secretory response to a meal.

6760 DOSE-RESPONSE RELATIONSHIP OF GRADED DOSES OF INTRAVENOUS HISTAMINE INFUSION ON GASTRIC ACID SECRETION IN MAN.

(E.) Naik, S. R.; Bajaj, S. C.; Goyal, R. K.; Chuttani, H. K. (Maulana Azad Medical Coll., New Delhi, India). *Digestion* 11(5-6):321-332, 1974.

The dose-response relation between i.v. histamine and gastric acid output was studied in nine healthy male adults of North Indian origin. The stomach contents were removed by nasogastric tube from the fasted subjects. Basal secretion was then measured and 50 mg of mepyramine maleate was administered i.m. Histamine (20-100 μg/kg/hr) was administered as histamine acid phosphate *via* constant i.v. infusion. Gastric secretions were collected every 15 min for three hr, and the acid content determined by titration with 1 N NaOH. Following i.v. histamine, the acid output gradually increased during the first 60 min and a steady state of acid secretion was reached for all dose levels during the second hr. Acid output increased significantly with increasing doses of histamine up to 80 μg/kg/hr; although acid output with 100 μg/kg/hr was greater than with 80 μg/kg/hr, this difference was not significant. Estimations of Vmax and the dose of histamine producing a response equal to 50% of the Vmax (K_m) by three different transformations of the Michaelis-Menten equation gave somewhat different values for these constants, and all values differed slightly from those estimated directly with curvilinear regression. The plot used by Hirschowitz gave the best results: V_{max} = 44.07 mEq/hr; K_m = 34.46 μg/kg/hr. Data analysis using dose of histamine independent of body weight gave a poorer fit to the regression line than the data obtained using histamine dose on the basis of body weight, suggesting that dosage should be determined on the basis of body weight. The value of K_m in the Indian subjects was almost six times the value obtained in Western subjects, indicating the relative insensitivity of the parietal cells of the former to histamine.

6761 EFFECT OF HYDROCORTISONE ON GASTRIC SECRETION AND SERUM GASTRIN IN DOGS.

(E.) Watson, L. C.; Reeder, D. D.; Thompson, J. C. (Univ. Texas Medical Branch, Galveston). *Surg. Forum* 24:354-356, 1973.

The effects of acute and chronic hydrocortisone treatment on the serum gastrin response to a standard meal and the acid secretion from a denervated pouch were studied in adult dogs. In the acute studies, the antrum was isolated and hydrocortisone acetate (50, 100, or 200 mg) was injected at 45-min intervals. The gastrin concentration in the venous blood was determined by radioimmunoassay. In the chronic studies, dogs with Heidenhain pouches were given a standard 500-g meat meal and the gastric secretions and serum gastrin concentrations were determined at 30-min intervals for three hr. Hydrocortisone was then injected i.m. at 100 mg/day for five days and the effects of food on acid secretion and serum gastrin levels were redetermined. Hydrocortisone produced no significant changes in serum gastrin levels (basal level 72 pg/ml) in the acute study. In the chronic study, the mean basal serum gastrin level was 98 pg/ml; after 5 days of hydrocortisone treatment, this rose significantly to 121 pg/ml. The three-hr integrated serum gastrin output after food was 10.2 ng/min/ml, which rose significantly to 16.1 ng/min/ml after five days of hydrocortisone treatment. The acid output after food was also significantly elevated after hydrocortisone. These findings provide information on the pathogenesis of steroid-induced ulcerations.

6762 EFFECTS OF 13-Nle-MOTILIN IN MAN — INHIBITION OF GASTRIC EVACUATION AND STIMULATION OF PEPSIN SECRETION.

(E.) Ruppin, H.; Domschke, S.; Domschke, W.; Wunsch, E.; Jaeger, E.; Demling, L. (Dept. Med., Univ. Erlangen-Nurnberg, Erlangen, West Germany). *Gut* 16(1):199-202, 1975.

The effects of i.v. 13-norleucine-motilin (13-nle-motilin) on gastric emptying and pepsin secretion were studied in three healthy men. Gastric fasting contents were removed from the fasted subjects by a gastric tube placed with its tip in the upper antrum. The stomach was then rinsed and 300 ml of test solution (10% mannitol in 0.5 M citric acid-phosphate buffer, pH 3.0) was instilled intragastrically. Polyethylene-^{14}C glycol served as a nonabsorbable marker. 13-Nle-motilin was administered on alternate days by continuous i.v. infusion in dosages of 0.1, 0.2, and 0.4 μg/kg-hr. The gastric contents were mixed by withdrawal and reinstillation. Gastric volumes, radioactivity of 15-min gastric samples, and pepsin activity in the samples were determined. Gastric emptying was slowed in a dose-dependent fashion by increasing doses of 13-nle-motilin. This was indicated by increasing 'half-lives' and 'starting indices' of the gastric emptying process, and by decreasing pyloric loss rates, respectively. The gastric pepsin output rose markedly from the basal level during i.v. 13-nle-motilin infusion. These results, in conjunction with previous data, suggest different susceptibilities of gastric and duodenal muscles to 13-nle-motilin. They also suggest that a common receptor site for secretin and motilin may be present in the stomach.

6763 THE COMBINED EFFECT OF PENTAGASTRIN AND MAGNESIUM ON GASTRIC ACID SECRETION IN MAN.

(E.) Christiansen, J. (Bispebjerg Hospital, Copenhagen, Denmark). *Gut* 16(1):203-205, 1975.

To determine the mechanism by which magnesium acts on gastric acid secretion, the combined effects of pentagastrin and magnesium on gastric acid secretion were studied in 10 healthy male and female volunteers. The gastric secretion was collected *via* a Levin tube in the fasted subjects, after which pentagastrin (0.5 μg/kg/hr) was administered over a three-hr period by constant i.v. infusion. After two hr of pentagastric infusion, when a secretory plateau had been obtained, magnesium sulfate (0.4 mEq Mg^{++}/kg/hr) was infused for one hr. The volume of the secretion collected for each 15-min period and the concentrations of H^+ and ^{51}Cr-labeled edetic acid were determined. Blood samples were also taken every 15 min for magnesium determination and at 0, 120, and 210 min for calcium determination. Pentagastrin infusion resulted in a secretory plateau which was unaltered during magnesium infusion; this applied to volume secretion as well as to acidity and acid output. Serum magnesium was elevated during magnesium infusion, but serum calcium concentration was unchanged throughout the experiment. The data could be explained by a dose-dependent relation between gastrin, magnesium, and calcium on acid secretion.

6764 EFFECT OF GASTRIC SECRETORY INHIBITORS ON THE GASTRIC MUCOSAL BARRIER.

(E.) O'Brien, P. E.; Carter, D. C. (Royal Infirm., Edinburgh, Scotland). *Gut* 16(6):437-442, 1975.

The effects of the synthetic prostaglandin 16, 16-dimethyl-E_2 methyl ester (16-diMe-PGE_2) and the histamine H_2-receptor antagonist, metiamide on the gastric mucosal barrier were studied in male dogs prepared with antrectomies and Heidenhain pouches. At the start of each of six 30-min experimental periods, basal solution or a test solution was instilled into the pouches of the fasted dogs. The fluid was sampled at the beginning and end of each period and assayed for Na^+ and H^+ concentrations. The basal solution consisted of 80 mEq/liter of HCl made isotonic with NaCl. The test solutions consisted of: basal solution with 20 mM sodium taurocholate replacing an equal amount of NaCl; and basal or taurocholate solution containing 30 μg/20 ml of 16-diMe-PGE_2 or 220 mg/20 ml of metiamide. In some experiments, the basal or taurocholate solution was instilled into the pouch and 16-diMe-PGE_2 (7.5 or 30 μg) or metiamide (75 mg) was given by i.v. injection. A low and stable ionic flux across the gastric mucosal barrier occurred in the basal state, a marked and highly significant increase in both H^+ back diffusion and Na^+ output being observed with the addition of taurocholate to the basal solution. When instilled into the Heidenhain pouch, 16-diMe-PGE_2 caused a marked increase in the rate of Na^+ output and a moderate increase in the rate of H^+ back diffusion from the pouch; both changes were highly significant. Bleeding from the pouch after administration of 16-diMe-PGE_2 occurred in four of six experiments. I.v. 16-diMe-PGE_2 did not alter the mucosal barrier or the response of the mucosa to sodium taurocholate. Metiamide did not affect the mucosal barrier or the response to taurocholate when given i.v. or instilled into the pouch. It is likely that the damaging effect of intragastric 16-diMe-PGE_2 reflects a specific biological action rather than the nonspecific chemical effect of a fatty acid. It is unlikely that histamine H_2 receptors play a significant role in the ionic fluxes observed after gastric mucosal barrier damage.

6765 SECRETIN EFFECT ON GASTRIN, GASTRIC SECRETION IN DOGS WITH CHRONIC ANTRAL STIMULATION.

(E.) Nasca, S.; Mignon, M.; Gramatica, L.; Accary, J. P.; Bonfils, S. (Unite Recherches Gastroenterologie, Institut National Sante, 75877 Paris Cedex 18, France). *Am. J. Physiol.* 228(6):1775-1781, 1975.

The effects of exogenous secretin on plasma gastrin levels and acid secretion were studied in dogs under conditions of chronic antral gastrin hyperproduction; the pepsigogue effect of secretin at various levels of secretin-induced acid suppression was also studied. Adult beagles were prepared with a Heidenhain pouch and an antral transposition onto the colon; gastrointestinal continuity was restored by an end-to-side gastrojejunostomy. Antrocolic transposition resulted in a marked increase in fasting plasma gastrin concentration and sustained high levels of acid secretion, acid output and plasma gastrin being significantly correlated in the fasting state. A marked increase in pepsin production accompanied the acid hypersecretion, but the pepsin output was not correlated with the plasma gastrin levels. Infusion 0.5, 1, and 2 U/kg/hr of secretin induced a dose-related depression in acid secretion and plasma gastrin; the reduction in acid output was two-fold greater than that in plasma gastrin and was related to reductions in both acid concentration and secretory volume. The fasting acid output correlated significantly with the remaining acid output during secretin infusion and with the maximal reduction in acid output after secretin. Despite the reduction in the secretory volume of the pouch after secretin, secretin at 0.5 and 1 U/kg/hr produced a 1.5- and 2-fold increase in pepsin output, resp. Secretin at 2 U/kg/hr decreased both the secretory volume and pepsin output. If the physiological release of secretin in dogs does not exceed the equivalent of the lowest dose studied, these results indicate that acid inhibition is a physiological action of secretin; the effect on the circulating gastrin concentration appears to be pharmacological.

6766 GASTRIC ACID RESPONSE TO ANTRUM DISTENSION IN MAN. *(E.)*

Bergegardh, S.; Olbe, L. (Kir. klin. II, Sahlgrenska sjukhuset, S-413 45 Goteborg, Sweden). *Gut* 16(1):171-176, 1975.

Gastric acid secretion in response to graded distension of the antrum was studied in six healthy subjects (four men), seven men with quiescent duodenal ulcers, 14 patients (12 men) with active duodenal ulcers, and five patients (two men) with gastric ulcers. A double lumen nasogastric tube was placed in the fasted subjects with its tip in the oral portion of the antrum. The antrum was distended by a balloon attached to the tip of the nasogastric tube and filled with increasing volumes of water (50, 100 and 150 ml) mixed with contrast medium. The stomach was continuously perfused with a phenol red solution. The volume and pH of the collected gastric contents were determined every 15 min, as was the amount of acid recovered and the phenol red concentration in the gastric contents. To determine the acid response to exogenous gastrin, pentagastrin was infused i.v. at 90 μg/hr for 45 min followed by 300 μg/hr for a further 45 min. In the healthy subjects, the mean basal acid secretion was 1.6 mEq/15 min, the mean peak acid output following pentagastrin was 9.1 mEq/15 min, and antrum distension did not significantly increase gastric acid secretion. In the quiescent duodenal ulcer patients, the mean basal acid secretion was 1.9 mEq/15 min, the mean peak acid output in response to pentagastrin was 12.0 mEq/15 min, and antrum distension did not significantly increase gastric secretion. In the active duodenal ulcer patients, the mean basal acid secretion was 2.3 mEq/15 min, the mean peak acid output following pentagastrin was 12.4 mEq/15 min, and antrum distension significantly increased gastric acid secretion. In the gastric ulcer patients, the mean basal acid secretion was 0.1 mEq/15 min, the mean peak acid output in response to pentagastrin was 5.1 mEq/15 min, and antrum distension resulted in a slight, but rarely significant, increase in gastric acid secretion. The pH of the gastric contents ranged from 1.8 in patients with active duodenal ulcers to 3.0 in those with gastric ulcers; the mean phenol red recovery ranged from 87% in normal subjects to 95% in gastric ulcer patients. The results indicate that the acid secretory effect of mechanical stimulation of the antrum is qualitatively different in healthy subjects and ulcer patients, with a marked acid response in patients with an active duodenal ulcer.

6767 INFLUENCE OF ANTRECTOMY ON GASTRIN RELEASE AND GASTRIC SECRETION IN CONSCIOUS MONKEYS.

(E.) Rosato, E. F.; Shumate, G. R.; Pollock, T. W.; Adair, L.; Rosato, F. E.; Brooks, F. P. (Philadelphia Veterans Admin. Hosp., Pa. 19104). *Surgery* 77(6): 817-824, 1975.

The plasma gastrin response to feeding and insulin stimulation was determined before and after precise antrectomy in conscious male rhesus monkeys (*Macaca mulatta*). The animals were prepared with gastric fistulas with modified Thomas cannulas. Chlorpheniramine maleate (10 mg) was injected s.c. 15 min before each experiment and histamine acid phosphate (0.02, 0.04, 0.08 mg/kg/hr) in saline was infused i.v. at a constant rate of 30 ml/hr. In the feeding stimulation trials, the animals were given a 30-min standard meal and the plasma gastrin levels were determined in the basal period and 10-180 min after feeding. In the insulin stimulation trials, gastric acid output and plasma gastrin were determined before and for eight 15-min periods after the i.v. injection of aqueous insulin (1-1.5 U/kg). Feeding resulted in a significant increase in plasma gastrin levels from basal levels of 107 pg/ml to 276 pg/ml. Stimulation with insulin increased the plasma gastrin levels to 182 pg/ml from a basal level of 93 pg/ml. Antrectomy reduced the basal gastrin concentrations and abolished the gastrin response to both feeding and insulin. It also abolished the acid secretory response to histamine and insulin. When three monkeys were antrectomized and maintained by duodenal feeding, the histamine acid secretory response was virtually abolished within 24 hr and did not recover within a four week period. In two animals, the addition of a submaximal dose of pentagastrin did not alter the response to histamine stimulation. Parietal cell architecture remained intact. The data indicate that the loss of secretory capacity secondary to antrectomy is due to the loss of circulating antral gastrin. The onset is prompt, is not related to reflux gastritis or parietal cell atrophy, and is not corrected by the administration of pentagastrin. The mechanism of this reaction is unknown.

6768 HEIDENHAIN POUCH DISTENSION AS A STIMULUS FOR ACID AND PEPSIN SECRETION. *(E.)*

Magee, D. F.; Hu, C. (Creighton Univ. Sch. Medicine, 2500 Calif. St., Omaha, Neb. 68178). *Ann. Surg.* 182(2):121-123, 1975.

The effects of Heidenhain pouch distension on the secretion of acid and pepsin were studied in six dogs with long-standing Heidenhain pouches and simple gastric fistulas. The pouches were distended with saline (30, 60 and 90 ml), the mean pressures within the pouch being elevated to 16.8, 21.0, and 22.5 cm of H_2O, resp. Beginning 30 min before the first distension, pentagastrin was given by continuous i.v. infusion (0.5 μg/min). Atropine sulfate (1 mg, i.v.) and pentolinium tartrate (1 mg/kg, i.m.) were given as single injections, and in some experiments a 0.5% solution of oxethazaine, a topical local anesthetic, was retained in the pouch for 10 min. There was a positive straight-line relation between the volume of saline added to the pouch and acid and pepsin secretion. I.v. pentagastrin did not alter the slope of the acid curve, but greatly increased the yield of acid at each level; pentagastrin had the opposite effect on pepsin secretion. Atropine significantly depressed the arithmetic regression lines for both acid and pepsin, but the calculated secretions at 0 distension were similar with and without atropine. Ganglionic blockade with pentolinium tartrate and oxethazaine rinse both depressed the acid response significantly, but neither had any effect on pepsin secretion. The data suggest that distension stimulates acid secretion from Heidenhain pouches *via* a cholinergic mechanism involving a local anesthetic-sensitive receptor and a synapse; the mechanism of distension-induced pepsin secretion appears to be different.

6769 INHIBITION OF GASTRIN-STIMULATED CANINE ACID SECRETION BY SHAM-FEEDING. *(E.)*

Sjodin, L. (Dep. Pharmacology, Karolinska Institutet, S-104 01 Stockholm, Sweden). *Gut* 15(11):73-80, 1974.

The inhibition of gastric secretion induced by sham feeding was characterized in five mongrel dogs with Heidenhain pouches and esophageal fistulas. Saline was continuously infused for one hr, after which pentagastrin (4 µg/kg/hr), histamine (100 µg/kg/hr), and/or bethanechol chloride (50 µg/kg/hr) was added to the infusion, which was continued for another four hr. After two hr of secretagogue administration, the dogs were sham fed for 10 or 60 min. The gastric juice was collected throughout the infusions *via* a cannula placed in the lower fundic portion of the main stomach. Pentagastrin-stimulated acid output from the vagally innervated main stomach increased significantly after 10 min of sham feeding, while acid secretion from the vagally denervated fundic pouches was depressed by an average of 33% after sham feeding. There was a corresponding reduction in the secretory volume. In the presence of histamine stimulation, sham feeding did not significantly affect the Heidenhain pouch secretion. When secretion was stimulated with a combination of pentagastrin and bethanechol chloride, the inhibitory effect of sham feeding was less pronounced than with pentagastrin alone. After these initial experiments, extra-gastric abdominal vagotomies were performed on four dogs and truncal vagotomies on three. The Heidenhain pouch acid responses to gastrin were decreased in most dogs after selective extra-gastric vagotomy, whereas the inhibitory effect of sham feeding was reduced or abolished by truncal vagotomy. The results are consistent with the hypothesis that vagal activity releases a hormone which has an inhibitory action on gastric acid secretion.

6770 STAGES IN THE RECOVERY OF FEEDING FOLLOWING VAGOTOMY IN RABBITS. *(E.)*

Rezek, M.; Vanderweele, D. A.; Novin, D. (Dept. Psychology, Univ. California, Los Angeles). *Behav. Biol.* 14(1):75-84, 1975.

The effects of vagotomy on the spontaneous intake of liquid and solid food was studied in 27 adult female rabbits. The animals were either chronically vagotomized or laparotomized (controls) and maintained on a free-feeding regimen. In the first experiment, the rabbits received duodenal cannulas and were fed a choice of greens, liquid, rabbit pellets during recovery from surgery. Food intake patterns were recorded before surgery and after the daily food intake had stabilized at 100 g or more per day. In the second experiment, the animals were treated as in the first experiment but did not receive duodenal cannulation and received solid and liquid food alternately, not simultaneously. Food intake patterns were recorded as soon as the animal began eating 800 g of solid food or 240 ml of liquid food per day, whether or not intake was stabilized. In the first experiment, the vagotomized animals took significantly longer to recover than the controls and mortality was 25% compared with 0% in the control group. After vagotomy, the animals were aphagic or severely hypophagic when offered only solid food, although they began to eat greens almost immediately. If greens were withdrawn, the animals again became aphagic or hypophagic, after which they spontaneously resumed liquid food intake; stable intake of solid food was not observed until several days later. Once recovered, the vagotomized rabbits showed a pattern of food intake characterized by significantly longer but less frequent meals than observed in the controls; the total daily food intake and feeding time were comparable in the two groups. The circadian pattern of alimentary behavior was largely unchanged after vagotomy. In the second experiment, the vagotomized rabbits showed a pattern of significantly more frequent and significantly smaller meals compared with controls and their own presurgery pattern. In both experiments, the animals shifted after several weeks to a pattern of longer, larger, and less frequent meals. The data indicate that the vagus nerve participates in meal patterning and appetite and that the effects of vagotomy change with time, probably as a result of reorganization of regulative controls. The data also indicate the importance of vagal afferent and efferent information in the control of eating.

6771 EFFECT OF INDUCED HYPERCALCEMIA ON GASTRIN RELEASE BY FOOD AND BY ANTRAL ALKALINIZATION IN MAN. *(E.)*

Basso, N.; Giri, S.; Fiocca, F.; Passaro, E., Jr.; Speranza, V. (Instituto Anatomia Chirurgica e Corso Operazioni, Univ. Roma, Italy). *Surg. Italy* 4(2):73-75, 1975.

The effects of induced hypercalcemia on gastrin release stimulated by food and antral alkalinization were studied in six healthy young men. Serum gastrin levels were determined under basal conditions and at 15-min intervals five hr following the ingestion of 150 cc of a saturated sodium bicarbonate solution (pH 7.5); after five days, this protocol was repeated with a three-hr Ca^{++} infusion (4 mg/kg/hr) preceding antral alkalinization and continuing throughout the experiment. In the second experiment, the fasted subjects were allowed to smell cooking food for 15 min and then were fed 250 ml of meat broth and 200 g of lean veal steak; five days later, this protocol was repeated during Ca^{++} administration as in the first experiment. After antral alkalinization, serum gastrin levels rose to 135% of basal values. The protein meal augmented the serum gastrin levels by 25% over basal values, while smelling cooking food decreased the gastrin levels to 85% of basal values. Calcium infusion alone increased basal gastrin levels by 25% during calcium infusion; antral alkalinization and the protein meal augmented basal gastrin levels by 110% and 120%, resp. Smelling cooking food also significantly increased serum gastrin levels in hypercalcemic subjects. The data suggest that calcium may be a mediator in all of the secretory mechanisms studied.

6772 EFFECTS OF NUTRITIONAL STATUS ON GASTRIC SECRETION AND COMPOSITION IN X-IRRADIATED RAT. *(E.)* D'Souza, D. W.; Vakil, U. K.; Sreenivasan, A. (Biochemistry Food Technology Div., Bhabha Atomic Res. Centre, Bombay, India). *Environ. Physiol. Biochem.* 4(6):270-279, 1974.

The effects of sublethal (400 r) and lethal (800 r) whole-body x-irradiation on the secretion and composition of gastric juice were studied in male Wistar rats maintained on diets with different protein levels (no protein, 8%, or 20%) with or without vitamin A supplementation (5000 IU retinyl palmitate/kg). Morphological changes in the stomachs of irradiated rats were also followed. In rats fed a nutritionally adequate diet, whole-body x-irradiation caused a progressive reduction in gastric acid secretion, with a maximum drop (50% in lethally irradiated rats) on the eighth day; free acidity and total acidity also decreased significantly. Specific peptic activity in gastric juice was 40% and 60% of control values in rats irradiated at 400 r and 800 r, resp.; pepsin and gastricsin activities also declined progressively up to the eight day post-irradiation. In sublethally irradiated rats, gastric juice secretion and proteolytic activities, resp., returned to normal levels on days 14 and 16 postirradiation; lethally irradiated rats did not survive beyond eight to 10 days. Radiation also resulted in a sudden rise (day one) in histamine levels in gastric juice, serum, and tissues, but values returned to normal by day three. While gross and severe degenerations were evident in the rat stomach two days postirradiation (400 r), stomach morphology was normal after eight days. Simultaneous deficiencies in protein and vitamin A had additive effects on gastric secretion and composition. Recovery from radiation injury dependend on the nutritional status of the animal. Protein-fasted animals did not survive beyond 14 days even when exposed to 400 r, and recovery was delayed at least six days in animals fed a low (8%) protein diet. The poor recovery in protein deficiency may be due to higher initial damage and subsequent increased sensitivity of tissues to x-irradiation.

6773 DEPRESSION OF ANTRAL AND SERUM GASTRIN CONCENTRATION BY FOOD DEPRIVATION IN THE RAT. *(E.)* Lichtenberger, L. M.; Lechago, J.; Johnson, L. R. (Veterans Admin. Wadsworth Hosp. Center, Wilshire and Sawtelle Blvd., Los Angeles, Calif. 90073). *Gastroenterology* 68(6):1473-1479, 1975.

The effects of food deprivation and refeeding on serum gastrin concentration and antral G-cell number were studied in male Wistar rats. In the first study, the rats were fed or fasted two, four or six days. In the second study, the rats were fasted for four days then refed for 30 min, three hr, 12 hr, one day, three days, six days, or nine days. In the third study, the rats were starved or fed (six days) powdered rat chow, a liquid diet, a high bulk nonnutritive diet, or a high bulk diet to which sucrose was added. At the completion of each study, serum and antral gastrin concentrations were determined by radioimmunoassay, and antral sections were examined by an indirect immunofluorescent antibody technique. A marked stepwise decrease in antral and serum gastrin levels was noted with increasing periods of starvation; by the fourth day, the antral gastrin decreased to one-third and the serum gastrin decreased to one-eighth of the fed levels. The number of antral cells reacting with fluorescent antigastrin antiserum was correspondingly decreased. After refeeding, the serum gastrin levels returned to normal levels within six days and the antral gastrin concentration and number of G-cells returned to normal within nine days. The rats fed the powdered rat chow or liquid diet for six days showed normal weight gain or maintenance and normal serum and antral gastrin levels. The fasted rats and those fed the high bulk nonnutritive diet lost weight to the same extent and showed similarly reduced antral and serum gastrin levels. Gastrin levels in the rats fed the sweetened high bulk diet were similar to those in the fasted rats. The data suggest that food in the gastrointestinal tract is necessary for the maintenance of normal serum and antral gastrin levels in rat. The effect of food is most likely attributable to its chemical constituents and not distention by bulk.

SECRETION AND METABOLISM

Pancreas

6801 IDENTIFICATION OF ENZYMES IN HUMAN PANCREATIC JUICE. *(Fr.)* De Caro, A.; Guy, O.; Crotte, C.; Figarella, C. (Unite de Recherche de Pathologie Digestive, U-31 INSERM, 46 chemin de la Gaye, F 13009 Marseille, France). *Arch. Fr. Mal. App. Dig.* 64(2):115-123, 1975.

Using fibroscopic techniques, human pancreatic juice was extracted by draining the duct of Wirsung from subjects not suffering from pancreatitis. The aim was to study human pancreatic enzymes and zymogens having been separated by polyacrylamide gel electrophoresis at pH 5.0 in a homogeneous system. A competitive inhibitor with trypsin was added to make clear the number of pancreatic zymogens in pancreatic juice with the artifacts of zymogen activation products. Pancreatic bands were identified by immunological techniques or by comparison with the electrophoretic migration of purified proteins. Two immunologically distinct chymotripsinogens, two immunologically identical proelastases, two trypsinogens, one procarboxypeptidase A, one procarboxypeptidase B, one nonspecific esterase, one prophospholipase, three isoamylases, and two isolipases (the latter two being glycoproteins) were reported. The main value of this work is the establishment in one operation of the semitotality of human pancreatic juices enzymatic content, to enable rapid comparisons among individuals.

6802 CIRCULATORY TURNOVER OF PANCREATIC AMYLASE. *(E.)* Ryan, J.; Appert, H. (Hahnemann Medical Coll. and Hosp., Philadelphia, Pa. 19102). *Proc. Soc. Exp. Biol. Med.* 149(4):921-925, 1975.

The plasma disappearance of i.v. infused radio-iodinated amylase and unlabeled porcine pancreatic amylase in pigs was examined. Radiolabeled (^{125}I) amylase and unlabeled pancreatic amylase were infused into 18 adult pigs of both sexes in order to determine the plasma half-life of the enzyme. Regardless of the parameter measured (radioactivity, enzyme activity, or concentration), the plasma removal curves could be resolved into three components when subjected to tracer analysis. The plasma half-life was estimated to be approximately three hr. Through the use of a recently developed radioimmunoassay specific for porcine amylase, the plasma concentration of amylase was calculated at 2.4 μg/ml. Based on the plasma concentration and half-life of amylase, the circulatory turnover of the enzyme was determined. Over a 2.4-hr period, 9.6 μg of pancreatic amylase/ml of plasma must reenter the circulation to maintain the enzyme at constant levels.

6803 BINDING OF BILE SALTS TO PANCREATIC COLIPASE AND LIPASE. *(E.)* Borgstrom, B.; Donner, J. (Dept. Physiological Chemistry, Univ. Lund, Sweden). *J. Lipid Res.* 16(4):287-292, 1975.

Equilibrium dialysis and gel filtration were used to study the interaction between colipase and bile salts in solution. Lipase and colipase were purified from porcine pancreas. The binding of taurodeoxycholate, glycodeoxycholate and taurocholate to colipase at 25 C in 150 mM of NaCl, 1 mM of CaCl$_2$ and 2 mM of Tris-HCl, pH 7.0, was measured by equilibrium dialysis. No binding took place below the critical micellar concentration for the bile salts. Above this concentration, the binding increased sharply for the dihydroxy conjugates, reaching values of 12 to 15 M/M of colipase. The binding of sodium dodecyl sulfate to colipase was found to be similar to that for bile salt and colipase; there was no binding below the concentration below the critical micellar concentration and there was a rapid increase above that point, reaching extrapolated figures of 40 to 50 M/M of colipase. A Sephadex G-100 column was equilibrated with a solution of 4 mM in ^{35}S-labeled taurodeoxycholate, 150 mM in NaCl, 1 mM in CaCl$_2$ and 2 mM in Tris-maleate, pH 7.0. Colipase (450 nM) dissolved in 0.5 ml of this solution was applied to the column. There was no apparent binding at low and high ligand concentrations. These results indicate that at physiological ionic strength and pH, conjugated bile salts bind micelles to colipase; 12 to 15 M/M of colipase for the dihydroxy conjugates and 2 to 4 for the trihydroxy conjugates. No binding of bile salts took place from monomeric solutions. Under the same experimental conditions, only 1 to 2 M of conjugated dihydroxy bile salts bound to pancreatic lipase. It is concluded that colipase may serve as a nucleus for micellization.

6804 THE INFLUENCE OF DETERGENTS AND TRYPSIN ON THE STIMULATION OF AMYLASE SECRETION BY EITHER PANCREOZYMIN OR SODIUM FLUORIDE IN THE PERFUSED RAT PANCREAS.

(Eng.) Robberecht, P.; Deschodt-Lanckman, M.; Camus, J.; Cristophe, J. (Univ. Brussels Medical Sch., B-1000 Brussels, Belgium). *Biochem. Pharmacol.* 24(17):1623-1629, 1975.

The effects of detergent and trypsin on the time course of pancreatic amylase secretion and on the stimulation of secretion by pancreozymin and sodium fluoride were studied *in vitro* using pancreatic tissue from male Wistar rats. Pancreas fragments were perfused for 2 hr with Krebs-Ringer bicarbonate buffer containing 10 mM of glucose and Trasylol (500 UIK/ml). In some experiments, digitonin, sodium dodecylsulfate, Triton X-100 or bovine trypsin (0.010, 0.025 or 0.050%) were added to the incubation medium for 30 min, after which the tissues were perfused with normal Krebs-Ringer-glucose medium for 30 min. Pancreozymin (320 U/ml) or NaF (10 mM) was added after this second 30-min period. α-Amylase in the perfusion medium and in the tissue fragments was estimated at 5-min intervals by the saccharogenic technique. In the absence of any of the added agents, the basal output of amylase decreased rapidly during the first 10 min, thereafter remaining stable at about 0.4% of the initial tissue content/5 min. The basal output increased with increasing concentrations of digitonin and sodium dodecylsulfate and with high concentrations of Triton X-100, but not with added trypsin. In the absence of any of these four agents, pancreozymin (7×10^{-9} M) rapidly stimulated amylase output, a two-fold increase over basal levels being attained within 20 min and thereafter remaining stable. This stimulation decreased progressively and finally disappeared after pretreatment with increasing concentrations of the three detergents or trypsin. NaF caused a biphasic stimulation of amylase secretion; the rapid initial peak was unspecific and related only to the NaF-induced rise in osmolarity, while the second, prolonged wave was due to NaF itself. Preexposure to detergent or to trypsin had no effect on the initial peak but caused a decrease in the second peak. However, sodium dodecylsulfate and digitonin in concentrations which abolished the secretory response to pancreozymin merely inhibited the second secretory effect due to NaF; Triton X-100 and trypsin were equally effective in abolishing the secretory responses to pancreozymin and NaF. The data suggest that the *in vitro* regulation of secretion by pancreozymin and NaF in intact acinar cells of the rat pancreas involves two distinct loci of a membrane-lipoprotein complex.

6805 PANCREATIC SECRETION OF TOTAL PROTEIN AND OF THREE HYDROLASES COLLECTED IN HEALTHY SUBJECTS VIA DUODENOSCOPIC CANNULATION.

(E.) Robberecht, P.; Cremer, M.; Vandermeers, A.; Vandermeers-Piret, M. C.; Cotton, P.; De Neef, P.; Christophe, J. (Univ. Brussels Medical Sch., Waterloo Blvd. 115, B-1000 Brussels, Belgium). *Gastroenterology* 69(2): 374-379, 1975.

The effects of secretin (1 Crick-Harper-Raper [CHR] U/kg), pancreozymin (CCK-PZ) (1 CHR U/kg), and cerulein (20 μg/kg) on the pancreatic secretion of total protein, amylase, lipase, and chymotrypsinogen were studied in 10 fasted male and female subjects free of gastrointestinal disease. The main pancreatic duct was cannulated to a depth of 2-3 cm, *N*-butylscopalammonium bromide being used to suppress duodenal peristalsis. The pancreatic juice was collected at 1-min intervals for up to 30 min; secretin injected i.v. at time zero and CCK-PZ or cerulein was injected 10-20 min later. Rapid i.v. secretin produced an immediate stimulation of protein and amylase secretion of 2-4 min duration and a sustained rise in flow rates. CCK-PZ produced a prompt 5- to 10-fold rise in the concentration and output of amylase and protein, the effect on volume secretion being relatively small compared with that on enzyme and protein secretion. The half-life of the CCK-PZ effect was 70-100 sec. Cerulein also stimulated the pancreatic secretion of protein and amylase; the pattern, magnitude, and duration of the response were the same as that produced by CCK-PZ. In addition, cerulein significantly stimulated the secretion of lipase and chymotrypsinogen. After stimulation of secretion, there was no significant change in the specific activity of chymotrypsinogen or in the ratios of the enzyme activities. The half-life of the effect of CCK-PZ and cerulein on pancreatic secretion was independent of flow rate and maximum protein output. The results are at variance with those previously reported in the cat and rabbit.

6806 GLUCAGON RELEASE: PARADOXICAL STIMULATION BY GLUCOSE DURING CALCIUM DEPRIVATION.

(E.) Leclercq-Meyer, V.; Rebolledo, O.; Marchand, J.; Malaisee, W. J. (Lab. Experimental Medicine, Univ. Brussels, 1000 Brussels, Belgium). *Science* 189(4206):897-899, 1975.

The paradoxical stimulation of glucagon release by glucose during calcium deprivation was studied in unfasted female albino rats. The pancreases of these animals were perfused *in situ* with Krebs-Ringer bicarbonate buffer containing bovine albumin (4 g/100 ml), glucose (3.3-16.6 mM, during the first 80 min), and calcium (2 mM, during the first 40 min). The effluent was assayed for glucagon and insulin by radioimmunoassay. Glucose (8.3 or 16.6 mM) stimulated insulin release during calcium administration but not during calcium deprivation. The output of glucagon during calcium administration was inversely related to the glucose concentration in the perfusion medium, calcium deprivation consistently provoking an enhancement of glucagon secretion. The effect of calcium deprivation was reversible. The positive secretory response of the pancreatic alpha cell to calcium deprivation consisted of two components: the first was characterized by an immediate, sharp, and short-lasting (about 4 min) peak of secretion which was most evident at the lowest glucose concentration; and the second, or late secretory phase, was absent at the lowest glucose concentration but was characterized by a long-lasting stimulation of glucagon release at higher glucose levels. It is suggested that the paradoxical stimulation of glucose during calcium deprivation, which is reminiscent of the abnormality of glucagon secretion observed in diabetes mellitus, results from a perturbation in the normal structural and functional bridging between pancreatic alpha and beta cells.

6807 COMPARISON OF SECRETIN AND VASOACTIVE INTESTINAL PEPTIDE ON PANCREATIC SECRETION IN DOGS. *(E.)* Konturek, S. J.; Thor, P.; Dembinski, A.; Krol, R. (Medical Acad., Krakow, ul. Grzegorzecka 16, Poland). *Gastroenterology* 68(6):1527-1535, 1975.

The action of the vasoactive inhibitory peptide (VIP) on pancreatic secretion under basal conditions and in response to secretin or cholecystokinin was studied in chronic pancreatic fistula mongrel dogs (three). Dogs were also provided with gastric fistulas. Graded i.v. doses of VIP and secretin produced a dose-related secretory response at 8 μg/kg/hr and 4 U/kg/hr, resp. The maximal bicarbonate response to VIP (0.75 mEq/30 min) was about 17% of that to secretin. Both cerulein (100 ng/kg/hr) and endogenous cholecystokinin released by a peptone meal potentiated pancreatic bicarbonate response similarly to secretin. From the dose-response curves to secretin alone and secretin plus VIP, Michaelis-Menten analysis showed competitive inhibition. Maximal inhibition occurred with 8 μg of VIP. These data indicate that VIP is a potent inhibitor of secretin-induced pancreatic secretion, and suggest that VIP and secretin share a common receptor site.

6808 SOMATOSTATIN SUPPRESSES SECRETIN AND PANCREATIC EXOCRINE SECRETION. *(Eng.)* Boden, G.; Sivitz, M. C.; Owen, O. E.; Essa-Koumar, N.; Landor, J. H. (Temple Univ. Health Sci. Center, Philadelphia, Pa. 19140). *Science* 190(4210):163-165, 1975.

The effects of somatostatin on the release of immunoreactive secretin (IRS) from the proximal small intestine and the pancreatic secretion of water, bicarbonate and protein were studied in conscious fasted dogs with long-term pancreatic fistulas. Synthetic somatostatin (200 μg, in the cyclic form) infused continuously for 30 min into a hind leg vein had no significant effect on IRS concentrations, but it significantly depressed pancreatic flow and the secretion of bicarbonate and secretin. In contrast, when somatostatin (200 μg/30 min) was infused concurrently with HCl (9.6 mEg/30 min, intraduodenally), the significant rise in IRS concentrations produced by HCl alone was completely abolished. The HCl-stimulated pancreatic flow rate and bicarbonate and protein secretion were also suppressed 67%, 72% and 64%, resp., by somatostatin. The inhibitory effects of somatostatin on IRS release and exocrine pancreatic secretion were short-lived and completely reversible. The data suggest that somatostatin may have a physiologic role in the secretion of pituitary, pancreatic, gastric, and duodenal hormones.

6809 INHIBITION OF PANCREATIC EXOCRINE SECRETION BY VINBLASTINE. *(E.)* Nevalainen, T. J.; (Dept. Pathological Anatomy, Univ. Turku, Finland). *Res. Exp. Med. (Berl)* 165(2):163-168, 1975.

The role of microtubules in pancreatic enzyme secretion was studied using the microtubule active agent vinblastine. Inbred BALB/c mice were given vinblastine sulfate and/or pilocarpine hydrochloride (20mg/kg) i.p., and amylase activity was determined in pancreatic homogenates. Vinblastine sulfate (200 mg/kg) given i.p. did not alter the pancreatic amylase content under the conditions of the experiment. Pilocarpine significantly decreased pancreatic amylase content within 2 hr. Pretreatment with vinblastine abolished this stimulatory effect of pilocarpine in a dose-dependent fashion at doses of 4, 40, and 400 mg/kg. These results are not unequivical proof of microtubule involvement in the secretory mechanisms in pancreatic acinar cells. Other effects of vinblastine must be considered, such as disturbances of amino acid metabolism, anticholenergic actions, and possible cell damage. The role of microtubules in the secretory mechanism of pancreatic acinar cells awaits further clarification.

6810 ENZYME SECRETION IN THE ABSENCE OF ZYMOGEN GRANULES. *(E.)* Rothman, S. S. (Dept. Physiology, Univ. California, San Francisco, Calif. 94143). *Am. J. Physiol.* 228(6):1828-1834, 1975.

The secretion of digestive enzymes was compared to the number of zymogen granules within the acinar cells in fasted and anesthetized adult male Holtzman rats. Pure pancreatic juice was collected from the cannulated common bile duct. Digestive enzyme secretion was studied before and after progressive degranulation of acinar cells produced by three s.c. doses of 0.8 mg/kg of methacholine chloride (a cholinergic stimulator). The kinetics of degranulation was estimated from the relative cell volume occupied by electron-opaque granules at various times using a random point-count stereological technique to examine tissue sections. Electron microscopic examinations showed that the three injections produced the almost complete disappearance of electron-opaque granules from secretory cells. Greatly augmented enzyme secretion was still observed: 10-fold greater for protein output overall; 7-fold greater for trypsinogen; and 25-fold greater for chymotrypsinogen. It is suggested that the movement of enzyme across the cell membrane into the duct system is from the cytoplasm, and that such movement is a final common step in the secretion of digestive enzyme derived from a variety of intracellular pools. However, the quantitative importance of the proposed transport mechanism in the normal process of protein secretion has yet to be determined.

6811 STUDIES ON HYPOXIA. X. EFFECTS OF SYNTHETIC POLYRIBONUCLEOTIDES ON PANCREAS FROM HYPOXIC AND CONTROL RATS: AN ELECTRON MICROSCOPIC AND BIOCHEMICAL STUDY. *(E.)* Kim, Y. G.; Han, S. S. (Univ. Michigan Sch. Medicine, Ann Arbor, Mich. 48104). *Exp. Mol. Pathol.* 23(1):43-58, 1975.

The effect of a mixture of synthetic polyadenylic and polyuridylic acids (poly A:U) on the structure and function of pancreatic acinar cells after prolonged hypoxia was studied. Sprague-Dawley rats were placed in a chamber with 12% O_2 and 88% N_2 for seven days. A homopolymer of poly (A:U) was injected i.p. at 1 mg/kg 24 hr before sacrifice. Pancreatic tissue was fixed with paraformaldehyde and OsO_4 for electron microscopy and stained with toluidine blue for light microscopy (nucleolar index was calculated from the number of nucleoli/number of nuclei x 100). For biochemical analysis, tissues were homogenized and counted by liquid scintillation spectrometry. Alpha amylase content was measured to indicate synthetic activity. Light microscopy showed that poly (A:U) treatment had little effect on controls, but in hypoxic rats there were smaller and fewer zymogen granules, the Golgi complex was enlarged, and the number and size of nucleoli was increased. The nucleolar index went from 73 in untreated to 88 in poly (A:U)-treated rats; there was a 21% increase in controls. In contrast, hypoxic rats showed an increase of from 61 in untreated to 85 in treated rats--a 40% increase. Ultrastructurally, poly (A:U)-treated control rats showed extensive development of the Golgi complex with condensing vacuoles of the distal portions of the cisternae increased in number. Treated hypoxic rats were similar. Occasionally, treated control rats had numerous zymogen granules in the rough endoplasmic reticulum cisternae. Biochemical tests showed that the DNA content of both control and hypoxic rats receiving poly (A:U) was 129% and 108%, resp., of those not receiving it. The difference between the hypoxic groups receiving and not receiving poly (A:U) was insignificant. Total protein in μg of protein/μg DNA after treatment was reduced to 68% and 75%, resp., in control and hypoxic groups from those not treated. Amylase content in treated rats was reduced to 89% in control and to 71% in hypoxic rats. Controls treated with poly (A:U) were lower in radioactivity (68%) than those untreated. The acid soluble fraction from treated controls was 63% of those untreated, while that of treated hypoxic rats was 54% of those untreated. Treatment produced an increase in radioactivity (172%) in hypoxic cells. It is concluded that poly (A:U) stimulates the functioning of the Golgi complex in rat acinar cells, consequently increasing protein synthesis, and to a greater extent in hypoxic rats.

6812 THE TRYPSINOGEN AND CHYMOTRYPSINOGEN CONTENTS OF THE PANCREAS DURING ACUTE EXPERIMENTAL PANCREATITIS OF THE RAT. *(E.)* Huttunen, R. (Dep. Anatomy, Univ. Oulu, 90220 Oulu, Finland). *Scand. J. Gastroenterol.* 10(2):177-180, 1975.

The fate of trypsinogen and chymotrypsinogen during inflammation of the pancreas was studied in rats. Long-Evans rats were divided into three groups: 1) controls; 2) rats killed 2 hr after induction of pancreatitis; and 3) rats killed 8 hr after induction. The time needed for maximal proenzyme activation was determined by incubating a mixture of the pancreatic supernatant, enterokinase and the buffer at 37 C. Aliquots were taken at various intervals, and free trypsin and chymotrypsin activities were estimated, using N-α-benzoyl-DL-arginin-4-nitroanilid hydrochloride and succinyl-L-phenylalanine-p-nitroanilide as substrates. Activation of chymotrypsinogen was more rapid than the activation of trypsinogen, with maximal activation occurring in 3 hr, while activation of trypsinogen required 17 hr. The content of both proenzymes decreased significantly during pancreatitis. In 8 hr the decline of trypsinogen content was 28.4% and that of chymotrypsinogen was 44.9% from the proenzyme content of the normal resting rat pancreas. No correlation was found between the trypsinogen and chymotrypsinogen content of the normal pancreas, but they were clearly correlated during pancreatitis. These data indicate that during pancreatitis, proenzymes and/or proteases are freed. It is suggested that the correlation between the proenzyme contents during inflammation reflects the amount of viable pancreatic tissue and the rate of synthesis.

SECRETION AND METABOLISM

Hepatobiliary Tract

6824 SCANNING ELECTRON MICROSCOPE STUDY OF DISSE SPACES AND CAPILLARIES IN RAT LIVER. *(Fr.)* Motta, P.; Porter, K. R. (Istituto di Anatomia Umana Normale, Universita di Roma, Viale Regina Elena 289, Roma, Italia). *Bull. Assoc. Anat.* 58(162):631-638, 1974.

Scanning electron microscopy (SEM) was used to study the relation between the capillaries and the hepatic cells in normal adult rats. Five anesthesized rats were injected through the left ventricle with a Tyrod solution containing oxygen and 0.1% procaine and heparin. Thirty seconds later a 2.5% buffered glutaraldehyde solution (0.18M, pH 7.3) was used to fix the organs. After dehydration, temperature of the pieces was lowered to the critical point in liquid CO_2. SEM demonstrated that the thin endothelial cells lining the rat sinusoids had a large number of fenestrations varying greatly in size. The presence of Kupffer cells and the existence of double layered endothelial cells could limit speed of filtration. The capillaries of the Disse space were obvious on all hepatic cells cemented to form biliary canals, yet there was never a communication between these canals and the sinusoids. In some places the Disse sinusoids actually became intracellular canaliculi, hence creating a network of interstitial lymph. The result is an increased exchange surface between hepatocytes, endothelial cells and the interstitial lymph.

6825 SCANNING ELECTRON MICROSCOPY DEMONSTRATION OF CILIA IN RAT INTRAHEPATIC BILE DUCTS. *(E.)* Motta, P.; Fumagalli, G. (Dept. Anatomy, Univ. Rome, Italy). *Z. Anat. Entwicklungsgesch.* 145(3):223-226, 1974.

Scanning electron microscopy was used to study cilia in the rat intrahepatic bile ducts. The lumen of portal and perilobular bile ducts and ductules appeared to be lined with numerous, small microvilli along with irregularly scattered, long cilia. These cilia arose perpendicularly as isolated, thin, cylindrical evaginations of the cell surface. They measured 0.2 μ in thickness and 0.5 μ in length. The surfaces of the cilia were finely granulated with some spherical swellings at the tips and along the surface. The cilia appeared more numerous in the larger portal ducts. It was suggested that these cilia are engaged in continual mixing and propulsion of the bile product or may serve in slowing bile flow, thus promoting its partial reabsorption. The occurrence of similar cilia in pancreatic ducts serves as a basis of speculation as to a common function to both organs.

6826 ASSESSMENT OF LYSOSOME MEMBRANE STABILITY. *(Rus.)* Pokrovskii, A. A.; Tutelian, V. A.; Kravchenko, L. W. (Inst. Nutrition, Moscow, USSR). *Biokhimiia* 40(3):545-551, 1975.

The effects of different concentrations of non-ionic detergents, triton X-100, triton X-305, BRIJ-35 and triton WR-1339, on the general and non-sedimentary activity of eight enzymes in liver lysosomes of male Wistar rats were determined. The enzymes investigated were: acid phosphatase, acidic DNase, acidic RNase, arylsulfatases A and B, glucuronidase, galactosidase, glucosidase, and acetylglucosaminidase. Lysosomal fractions were isolated by differential centrifugation. Subsequently, 5 ml portions of lysosomal suspension were mixed with 0.1 ml portions of 0.05, 0.1, 0.5, 1.0 and 2.0% detergent solutions, incubated for 15 min at 25C, and centrifuged. The non-sedimentary activity was determined by spectrophotometry. Only triton X-100 (0.1%) caused full release of lysosomal enzymes. The degree of release of acidic DNase, B-galactosidase, B-glucuronidase, and acid phosphatase were considerably higher than of the other enzymes. A method was developed for serial investigation of the stability of lysosomal membranes in animals with various physiological and pathological conditions. The method consisted of treating isolated structures with increasing concentrations of triton X-100 (0.025, 0.05, and 0.01%) with the subsequent determination of non-sedimentary activity marking the enzymes.

6827 DETERMINATION OF THE SPECIFIC BLOOD FLOW OF THE LIVER BY INHALATION OF RADIOACTIVE RARE GASES. *(E.)* Schmitz-Feuerhake, I.; Huchzermeyer, H.; Reblin, T. (Medizinische Hochschule Hannover, 3 Hannover-Kleefeld, Karl Wiechert Allee 9, West Germany). *Acta Hepato-Gastroenterol.* 22(3):150-158, 1975.

A new technique involving the inhalation of radioactive xenon was used to study the specific blood flow of the liver in human livers of known fat content. The subjects inhaled a mixture of ^{133}Xe and air at a concentration of 1 μCi/ml for 2.5 min. Scintillation detectors were arranged over the liver and spleen for the registration of 81 keV-γ-radiation. A double isotope measurement using ^{133}Xe parallel to radioactive krypton was employed to determine the dependence of the partition coefficient on the liver fat content. Using the ^{133}Xe inhalation technique, an average blood flow of 91 ml/100 g/min was found in people with healthy livers; the reproducibility of the values was 5%. The xenon wash-out was delayed in cirrhotic livers, the blood flow being significantly decreased to an average value of 45 ml/100 g/min. A delayed wash-out of xenon was also found in major fatty livers due to xenon's high affinity for fat. Thus, a retarded wash-out of xenon can mean a reduced blood flow or a major fatty degeneration. The double isotope measurements in patients with known liver fat content showed a good conformity in livers with fat contents less than 10%. In the case of higher fat content, it was not possible to determine the blood flow with satisfactory accuracy due to an inability to accurately determine the partition coefficient. The method should therefore be suitable only for relative measurements.

6828 BIOPHARMACEUTICAL STUDY OF THE HEPATOBILIARY TRANSPORT OF DRUGS. III. BINDING CHARACTERISTICS OF BROMPHENOL BLUE AND AMARANTH TO THE LIVER CYTOPLASMIC Y AND Z BINDING PROTEINS *IN VITRO. (E.)* Takada, K.; Narumiya, O.; Muranishi, S. (Faculty Pharmaceutical Sciences, Kyoto Univ., Yoshida-shimoadachi-cho, Sakyo-ku, Kyoto, Japan). *Chem. Pharm. Bull. (Tokyo)* 23(4):729-735, 1975.

The binding properties of the Y and Z binding proteins for two organic anionic compounds (bromphenol blue and amaranth) were investigated by modification of the proteins with sulfhydryl-blocking reagents, amino acid group modifiers, and fluorescent probe. Isolated perfused livers were obtained from male Sprague-Dawley rats. The binding of bromphenol blue appeared to be independent of ionic strength. With greater pH, the binding of this compound with both proteins decreased. Amaranth had a higher affinity for the Y and Z proteins (5.67 x 10^4 and 1.43 x 10^4 M^{-1}, resp.) than for bovine serum albumin (1.33 x 10^4 M^{-1}). There was a reverse result obtained, however for bromphenol blue, which had higher affinities for bovine serum albumin (6.58 x 10^5 M^{-1}) than for the Y or Z proteins (1.29 x 10^5 and 1.39 x 10^5 M^{-1}, resp.). There was no significant inhibition of binding observed by any of the sulfhydryl blocking reagents (*p*-chloromercuribenzoic acid, *p*-chloromercuribenzene sulfonic acid, N-ethylmaleimide, and iodoacetamide) on binding of either amaranth or bromphenol blue to either the Y or Z proteins. The binding of bromphenol blue to either protein was inhibited by the amino group modifiers: succinic anhydride (51.9 and 91.2%); maleic anhydride (96.8 and 84.5%); and acetic anhydride (50.5 and 24.2%), for the Y and Z proteins, resp. The binding of amaranth was not so greatly inhibited. Fluorescent probe showed that the binding of amaranth to the Y protein especially and of bromphenol blue to a lesser extent to both proteins was mainly due to hydrophobic forces. It is concluded that plasma protein-binding does not determine hepatobiliary transport of organic anionic compounds.

6829 Z PROTEIN IN HEPATIC UPTAKE AND ESTERIFICATION OF LONG-CHAIN FATTY ACIDS. *(E.)* Mishkin, S.; Stein, L.; Fleischner, G.; Gatmaitan, Z.; Arias, I. M. (Albert Einstein Coll. Medicine, Bronx, N.Y. 10461). *Am. J. Physiol.* 228(6):1634-1640, 1975.

Hepatic uptake and esterification of fatty acid were measured following administration of flavaspidic acid to determine whether binding of long-chain fatty acids to Z protein is obligatory in these processes. Fatty acid radioactivity was bound to Z protein in liver *in vivo* after administration of [^{3}H]-oleate (20 μCi) to male Sprague-Dawley rats. The same activity was found in isolated perfused rat livers. Oleate radioactivity bound to Z protein was effectively reduced by pretreatment with flavaspidic acid (340 μM/kg) by 90.2% and by 85.0% in intact and perfused livers, resp. However, plasma clearance, hepatic uptake and esterification of [^{3}H]oleate were not altered by pretreatment with flavaspidic acid. Infusion of flavaspidic acid (340 μM/kg) or BSP (360 μM/kg) increased uptake of [^{3}H]oleate at least twofold, and oleate esterification was decreased by 15 to 30% in isolated perfused livers. These results indicate that Z protein may function as an organic ligand-binding protein, and may be important in fatty acid esterification.

6830 COMPARATIVE UPTAKE OF SULFOBROMOPHTHALEIN BY ISOLATED KUPFFER AND PARENCHYMAL CELLS. *(E.)* Stege, T. E.; Loose, L. D.; Di Luzio, N. R. (Tulane Univ. Sch. Med., New Orleans, La.). *Proc. Soc. Exp. Biol. Med.* 149(2):455-461, 1975.

The effects of serum, albumin, and varying concentrations of ethanol on the uptake of sulfobromophthalein (BSP) by hepatic parenchymal and Kupffer cells isolated from male Sprague-Dawley rats were studied. The isolated cells were suspended in bicarbonate-free Hanks' balanced salt solution containing 5, 10, or 20% isologous rat serum, 2.5, 5, or 10% albumin, or 100, 200, or 400 mg of ethanol/100 ml. BSP (10 μg) was then added to the incubation mixture. Cellulose powder thin-layer chromatography was used to determine the cellular concentrations of BSP and its glutathione conjugate (BSP-GSH). The isolated Kupffer cells did not take up BSP from the incubation medium, and did not form BSP-GSH. The parenchymal cells, on the other hand, showed a maximum BSP uptake of 49.8 μg/10^7 cells after 15 min incubation; after 60 min of incubation, the incubation medium contained no free BSP but did show the presence of BSP-GSH. The rate of and maximum uptake of BSP by the parenchymal cells was inversely related to the concentration of serum or albumin in the incubation medium; the inability of the Kupffer cells to take up BSP from the medium was unaltered by variations in the cell number or in serum concentration. Ethanol had no direct cytotoxic effects and did not alter BSP uptake by the isolated parenchymal cells. The results indicate that the uptake and conjugation of BSP are exclusive functional expressions of the hepatic parenchymal cell population. They also illustrate the potential use of isolated cells as a model system for the rapid and direct assessment of hepatotoxic agents on hepatic cell populations and functions.

6831 SULFATION OF BILE SALTS: A NEW METABOLIC PATHWAY.

(E.) Stiehl, A. (Medizinische Universitatsklinik, Heidelberg, Federal Republic of Germany). *Digestion* 11(5-6):406-413, 1974.

The metabolism of sulfated bile salts in man and the rat is discussed, as is the effect of sulfation on the toxic properties of bile salts. The sulfation of bile salts renders them polar and more water soluble, thus altering their metabolism, excretion, and toxicity. In human bile, considerable amounts of lithocholate can be sulfated both in health and disease, lithocholate being preferentially sulfated in comparison with other bile salts. The urinary excretion of sulfate esters of bile salts represents an important excretory mechanism in patients with cholestatic liver disease. For the most part, only one or two hydroxyl groups of the bile salts excreted in the urine are sulfated. The sulfate bile salts are excreted in the urine more rapidly than nonsulfated bile salts, a phenomenon which may be partially due to the diminished protein binding and/or decreased tubular reabsorption of the former. Although sulfation of bile salts is only known to occur in the liver, it is possible that sulfation by the kidney might contribute to the large amounts of bile salt sulfates in the urine. It is unlikely that sulfated bile salts are responsible for the pruritus in patients with cholestasis. In the rat, less lithocholate is sulfated than in man, although in the rat as in the human the sulfation of bile salts is an important metabolic pathway in the cholestatic liver. Sulfate esters of lithocholate are more rapidly eliminated in the feces and urine of the rat than are the
nonsulfated compounds and it is likely that sul
of lithocholic acid could enhance its fecal eli
tion. Most of the sulfated bile salts in the r
present as taurine or glycine conjugates, the e
matic hydrolysis of which is slower than with t
sulfated compounds. Sulfated bile salts appear
have considerably less liver toxic properties t
the nonsulfated compounds; thus, the sulfation
bile salts becomes important in patients with c
tasis in whom elevated bile salt concentrations
cause liver damage.

6832 INCORPORATION OF ALA-^{14}C IN CIRCULATI
BILIRUBIN AND HEMOGLOBIN HEME OF HEPA

TOMIZED DOGS. *(E.)* Royer, M.; Sfarcich, D. (P
clinico A. Posadas Haedo, Argentina). *Acta Hep*
Gastroenterol. 22(3):139-144, 1975.

The formation of bilirubin from nonhemoglobin s
was studied in intact and hepatectomized mongre
dogs. The fasted dogs were hepatectomized or s
jected to common bile duct cannulation and inje
i.v. with 50 μCi of delta amino-levulinic acid-
(ALA-^{14}C). Blood samples were obtained at 3-hr
vals for 15 hr from the hepatectomized dogs and
and bile samples were taken at 14, 45, 105 and
min, and at 4, 6 and 9 hr from the intact dogs.
radioactivity of bilirubin and heme in the bloo
measured after crystallization. In the hepatec
animals, the blood bilirubin-^{14}C concentration
3 to 6 hr after ALA-^{14}C administration, then sl
declined. During this time, the hemoglobin hem
dioactivity was much lower and rose sluggishly;
bilirubin specific activity was several hundred
that of the hemoglobin heme and the incorporati
isotope was also much greater for the bilirubin
the intact dogs, i.v. ALA-^{14}C produced similar
sults, but the amount of bilirubin-^{14}C produced
hr in the hepatectomized animals was only about
of the total blood bilirubin-^{14}C in the intact
mals. Nonhemoglobin bile production in the int
dogs was only about 4.2% of the total bile prod
tion. The results indicate that bilirubin is p
duced outside the liver by a mechanism other th
breakdown of hemoglobin.

6833 PRODUCTION OF URIC ACID IN THE HUMAN
DURING PARENTERAL ADMINISTRATION OF F

TOSE. *(Ger.)* Grunst, J.; Dietz, G.; Wicklmayr
Motz, S.; Eisenburg, J.; Mehnert, H.; Hepp, K.
(I. Med. Klinik, Univ. Munchen, Germany). *Vehr*
Dtsch. Ges. Inn. Med. 80:487-491, 1974.

Uric acid concentrations were measured in the h
vein and arterial and peripheral venous blood i
normal subjects who had fasted for 15 hr before
ing, and after an i.v. infusion of a 10% fructo
solution. After a 30 min control period, 10 g
fructose was infused in the first five min and
0.5 g/kg/hr. Liver blood flow was measured wit
^{135}Xe inhalation technique; fructose, glucose,
phate, lactate, and pyruvate concentrations wer
termined every 10 min; and, in some cases, rena
cretion of uric acid was studied. Arterial fru
concentrations reached a peak of about 3 mM fiv
after infusion was begun and then decreased to

ncentration in the hepatic vein was about 1 mM
 The uric acid concentration in the hepatic
ncreased immediately after fructose infusion
gun, reached a peak after 20-30 min, and then
 to decrease. Arterial concentrations of uric
emained essentially unchanged, as did uric acid
 in peripheral venous blood. Liver blood flow
sed from 85.2 to about 100 ml/100 g liver/min
fructose infusion and then decreased again to
itial value. Fructose infusion increased uric
roduction, obtained by multiplying the differ-
n uric acid concentrations between arterial
and that from the hepatic vein by liver blood
about 8-fold (from 0.07 to 0.6 mg/100 g liver/
ithin 10-20 min. After administration of fruc-
the lactate concentration increased in blood
e hepatic vein, reaching 2.5 mM in the arter-
od, a level that would be expected to have an
 on renal uric acid excretion. During fruc-
fusion, uric acid excretion increased to about
the basal values. It is suggested that ATP,
rdinarily inhibits 5-nucleotidases, is utilized
hexokinase-catalyzed phosphorylation of fruc-
 fructose-1-phosphate. Elimination of this
ion increases the breakdown of nucleotides,
ng in increased uric acid synthesis.

UDP GLUCURONYLTRANSFERASE AND PHENOLSULF-
OTRANSFERASE FROM RAT LIVER IN VIVO AND
O--IV. SPECIES DIFFERENCES IN HARMOL CONJU-
AND ELIMINATION IN BILE AND URINE IN VIVO.

 Mulder, G. J.; Bleeker, B. (Dept. Pharmacol-
ate Univ. Groningen, Groningen, The Nether-
 Biochem. Pharmacol. 24(16):1481-1484, 1975.

conjugation and the subsequent elimination of
sulfate and harmol-glucuronide were studied
 Swiss mice, guinea pigs, rabbits, rats and
The cystic duct from the gallbladder was

gularis externa and urethra were cannulated.
d urine were collected fractionally during the
llowing the i.v. injection of harmol
kg); in the mice and rabbits, urine was coll-
rom the bladder at the end of the experiment
than in fractions during the experiment.
as no correlation between the rate of bile
ion and the biliary excretion of the harmol
tes, nor between the rate of urine production
 urinary excretion of the conjugates. The
and guinea pig nearly exclusively conjugated
mol with glucuronate, whereas the cat predom-
 synthesized the sulfate conjugate. The mouse
 synthesized both conjugates at high rates,
se producing more of the glucuronide conju-
d the rat producing more of the sulfate
te. In all species studied, about 21% of the
d harmol was excreted in the urine in conju-
orm. In the rabbit, about 9% of the injected
s excreted in the bile, while in the other
 about 33-58% of the injected dose was ex-
in the bile. Except for the rabbit, most of
ected harmol was excreted in the bile, harmol-
nide being excreted predominantly in the bile
bbit being an exception) and the harmol-
 being excreted to a large extent in the

urine. In most species, the biliary excretion of the harmol conjugates occurred during the first 30 min after injection; in the cat, biliary excretion of harmol occurred during the first 60 min. The data suggest that biliary excretion requires a high liver concentration of the relevant compound for a high excretory rate.

6835 RATE-LIMITING FACTORS IN THE OXIDATION OF ETHANOL BY ISOLATED RAT LIVER CELLS. *(Eng).*

Meijer, A. J.; Van Woerkom, G. M.; Williamson, J. R.; Tager, J. M. (Lab. Biochemistry, Univ. Amsterdam, Plantage Muidergracht 12, Amsterdam, The Netherlands). *Biochem. J.* 150(2):205-209, 1975.

To determine whether the rate-determining factor during ethanol oxidation is the activity of the shuttles or flux through the phosphorylating electron-transport chain, ethanol oxidation by liver cells isolated from starved (24 hr) and *ad libitum*-fed male Sprague-Dawley rats was studied. Ethanol uptake and oxidation were measured in the presence of malate, DL-cycloserine, carbonyl cyanide *p*-trifluoromethoxyphenylhydrazone, and amytal. Malate caused a marked cycloserine-sensitive stimulation of ethanol oxidation in the liver cells from the starved rats and a small increase in glucose production; oxygen uptake was not increased. The addition of carbonyl cyanide *p*-trifluoromethoxyphenylhydrazone to the cells from the starved rats did not increase ethanol consumption, unless the cells were preincubated with lactate and guinolinate. At carbonyl cyanide *p*-trifluoromethoxyphenylhydrazone concentrations greater than 6.6 μM, ethanol consumption was inhibited and there was a concomitant decrease in respiratory rate and an increased leakage of lactate dehydrogenase into the medium. Lactate stimulation of ethanol oxidation was shown to have two components: stimulation by an increased energy demand owing to glucose synthesis which was sensitive to quinolate; stimulation by increased activity of the malate-aspartate cycle because of increased malate and aspartate concentrations, which was insensitive to quinolate. The addition of dehydroxyacetone to the liver cells from the starved animals stimulated ethanol uptake by 45% and increased the glycerol 3-phosphate content three-fold. Amytal (1-4 mM) inhibited ethanol uptake by 50% and caused a progressive switch of dehydroxyacetone metabolism from glucose to lactate formation. The rate of ethanol consumption by the cells from the fed rats was two-fold greater than that observed in the cells from the starved rats, and the cellular concentrations of malate, aspartate, and glycerol 3-phosphate were much higher in the former than in the latter. Malate stimulated ethanol consumption in the fed rats, but this effect was inhibited by quinolinate. Carbonyl cyanide *p*-trifluoromethoxyphenylhydrazone also stimulated ethanol oxidation in the fed rats, but malate was ineffective. Thus, in the cells from the starved rats, the transfer of reducing equivalents from the cytosol to the mitochondria appears to be regulated by the intracellular concentrations of the intermediates of the malate-aspartate and glycerol 3-phosphate cycles, as well as by flux through the respiratory chain.

6836 CHANGES IN SOME CLINICAL CHEMICAL PARAMETERS IN THE SERUM OF SUBJECTS GIVEN ALCOHOL FOLLOWING CONTINUOUS INHALATION OF CARBON DISULFIDE. *(Ger.)* Freundt, K. J.; Lieberwirth, H. (Institut Toxikologie und Pharmakologie, Universitat, D-8700 Wurzburg, Koellikerstrasse 2, Germany). *Zentralbl. Arbeitsmed.* 24(9):266-271, 1974.

Serum cholesterol, Ca^{++}, inorganic phosphate, total bilirubin, albumin, total protein, uric acid, nonprotein nitrogen, glucose, LDH, alkaline phosphatase, and SGOT were measured in 11 normal males, aged 20-32 yr and weighing 64-98 kg, who were exposed to carbon disulfide (CS_2) concentrations of 20, 40, or 80 ppm for eight-hr periods once or on two or five consecutive days. These subjects were fed a standard diet and, to maintain a blood alcohol level of approximately 0.07%, 0.57 mg/kg ethanol in 3.01 ml/kg orange juice at the beginning of the test period and 0.047 ml/kg ethanol in 0.18 mg/kg orange juice every 15 min thereafter for eight hr. Controls consisted of subjects fed the same diet who were not exposed to CS_2 or who were exposed to 20 ppm CS_2 but given no alcohol. Total serum bilirubin increased and blood glucose decreased in subjects given alcohol and exposed to 80 ppm CS_2 for eight hr. Total serum bilirubin, albumin, total protein, uric acid, and alkaline phosphatase increased in subjects given alcohol 16-24 hr after an eight-hr exposure to 20 ppm CS_2. When subjects were exposed to 20 ppm CS_2 for eight-hr periods on each of five consecutive days and given alcohol over the last eight-hr exposure period, total serum bilirubin increased and glucose and SGOT decreased. Serum glucose concentrations also decreased in controls who were given alcohol but were not exposed to CS_2. All of these changes were significant ($0.1 < p < 0.05$), but values were above the normal range in only a few cases. No changes occurred in any of the parameters measured when subjects were exposed for 8 hr to 40 ppm CS_2 and given alcohol or when they were exposed to 20 ppm CS_2 for 8 hr without alcohol. These findings indicate that occupational exposure to CS_2 concentrations of 20 ppm or less in subjects who drink moderate amounts of alcohol causes no pronounced changes in any metabolic reactions routinely measured.

6837 THE EFFECT OF ETHYL ALCOHOL ON HEME AND PORPHYRIN SYNTHESIS IN RAT LIVER. *(Ger.)* Held, H. (Med. Univ. Klinik, Tubingen, Germany). *Verh. Dtsch. Ges. Inn. Med.* 80:481-484, 1974.

Administration of 2 g/kg ethanol p.o. to rats which had been fasted for 48 hr doubled or tripled Δ-aminolevulinic acid (ALS) synthetase activities within three hr but had no effect on ALS dehydratase or drug-metabolizing decarboxylase, as measured by hexobarbital degradation and the cytochrome P-450 concentration. The ALS synthetase activity returned to normal 6 hr after administration of ethanol. From eight to 24 hr after administration of ethanol, the total porphyrin concentration in the livers of these rats was increased significantly to a maximum of 75% of the initial value. As anticipated, in fasting rats given 80 mg/kg phenobarbital 48 hr before administration of ethanol, hexobarbital decarboxylase was induced and cytochrome P-450 concentrations doubled or tripled. The increase in ALS synthetase activities which occurred after administration of ethanol in phenobarbital-treated rats was greater than that in rats given ethanol alone and reached as high as 10 times the original values. However, 16 hr after injection of phenobarbital, enzyme activities had returned to their initial levels. These findings suggest that phenobarbital sensitizes the liver to ethanol. The induction of ALS synthetase cannot be due to changes in cytochrome P-450 concentrations in the hepatocytes but is probably due to changes in intermediary metabolism in the liver.

6838 EFFECT OF CHRONIC ETHANOL INGESTION ON FATTY ACID OXIDATION BY HEPATIC MITOCHONDRIA. *(E.)* Cederbaum, A. I.; Lieber, C. S.; Beattie, D. S.; Rubin, E. (Mount Sinai Sch. Medicine, City Univ. New York, N.Y. 10029). *J. Biol. Chem.* 250(13): 5122-5129, 1975.

To further investigate the pathogenesis of fatty liver, the effect of chronic ethanol ingestion was studied in liver mitochondria isolated from male Sprague-Dawley rats. Oxygen uptake with various fatty acids as substrates was measured. State 3 uptake was depressed to a greater extent (75.80 and 54.2 natoms/min/mg of protein for control and ethanol-treated, resp.) than State 4 respiration (20.93 and 18.0 natoms/min/mg of protein, resp.), using 15 µM of palmitoyl-l-carnitine as a substrate. Values with other fatty acids as substrates were similar. CO_2 production from palmitate was reduced 37% in mitochondria from ethanol-fed rats, comparable to the 32% decrease seen in State 3 oxygen consumption. CO_2 production from octanoate was reduced 20% by ethanol feeding, similar to the 17% decrease in State 3 oxygen consumption. Palmitoyl coenzyme A (CoA) synthetase activity was not affected by ethanol feeding. Carnitine palmitoyltransferase activity was stimulated 30%. Ethanol feeding had no effect on the endogenous rate of ketone body production. However, the addition of palmitoyl-l-carnitine or palmitate increased ketone body production about 4-fold. Fatty acid oxidation under anaerobic conditions, with the use of artificial electron transport acceptors to reoxidize NADPH, was studied. In the presence of fluorocitrate, ketogenesis and formazan production were increased by chronic ethanol feeding. It is concluded that chronic consumption of ethanol leads to persistent impairment of mitochondrial oxidation of fatty acids to CO_2, even though oxidation of fatty acids to acetyl-CoA is not decreased.

6839 EFFECT OF ACETALDEHYDE ON FATTY ACID OXIDATION AND KETOGENESIS BY HEPATIC MITOCHONDRIA. *(E.)* Cederbaum, A. I.; Lieber, C. S.; Rubin, E. (Mount Sinai Sch. Medicine, City Univ. New York, N.Y. 10029). *Arch. Biochem. Biophys.* 169(1): 29-41, 1975.

To determine whether acetaldehyde may play a role in ethanol-induced steatosis, the effects of acetaldehyde on fatty acid oxidation by isolated rat liver mitochondria were studied. The mitochondria were incubated with 0.6 to 12.0 mM of acetaldehyde and the effects on mitochondrial oxygen consumption, CO_2

production, ketone body production, acetyl CoA content, and palmitoyl-CoA synthetase and carnitine-palmitoyltransferase activity were determined. State 3 (coupled) oxygen consumption was inhibited by acetaldehyde in concentrations as low as 0.6 mM, while state 4 (resting) respiration was significantly inhibited only by 12 mM of acetaldehyde. Ethanol (12, 40 and 80 mM) had no effect on oxygen consumption. Acetaldehyde also caused a decrease in the respiratory control ratio associated with the oxidation of palmitoyl-1-carnitine and palmitoyl CoA; ethanol had no such effect. Acetaldehyde depressed ketone body production as well as the content of acetyl CoA during palmitoyl-l-carnitine oxidation, acetaldehyde being considerably more inhibitory toward fatty acid oxidation than was acetate. Oxygen uptake was depressed by acetaldehyde to a slightly, but consistently, greater extent in the absence of fluorocitrate than in its presence. The formation of CO_2 from palmitate was strikingly reduced by acetaldehyde; CO_2 production was much more sensitive to inhibition by acetaldehyde than was oxygen consumption. The inhibitory effect of acetate on CO_2 production was considerably less than that of acetaldehyde, and the oxidation of acetate to CO_2 was depressed by acetaldehyde. The results suggest that acetaldehyde-induced inhibition is not mediated by acetate, and that the inhibition of fatty acid oxidation is not due to any effect on the activation or translocation of fatty acids into the mitochondria. Acetaldehyde appears to inhibit β-oxidation, citric acid cycle activity, and the respiratory-phosphorylation chain. Neither the activities of palymitoyl CoA synthetase nor carnitine palmitoyltransferase appear to be rate limiting for fatty acid oxidation. The inhibition of fatty acid oxidation by metabolites of ethanol oxidation (acetaldehyde) may contribute to the steatosis observed after chronic ethanol treatment.

6840 ACETALDEHYDE OXIDATION BY HEPATIC MITOCHONDRIA: DECREASE AFTER CHRONIC ETHANOL CONSUMPTION.

(E.) Hasumura, Y.; Teschke, R.; Lieber, C. S. (Veterans Admin. Hosp., Bronx, N.Y. 10468). *Science* 189(4204):727-729, 1975.

The effects of chronic ethanol feeding (36% of the total calories in a nutritionally adequate diet for 4 to 5 wk) on the capacity of intact liver mitochondria to oxidize acetaldehyde and the activity of aldehyde dehydrogenase in disrupted mitochondria were studied in pair-fed female Sprague-Dawley rats. Chronic ethanol consumption resulted in a significant reduction in the rate of acetaldehyde metabolism by intact mitochondria *in vitro*. This was associated with decreased mitochondrial respiration with acetaldehyde as substrate. The addition of fatty acids and other substrates for NAD-linked dehydrogenases in mitochondrial respiration further decreased the rate of acetaldehyde oxidation. In contrast, in disrupted mitochondria supplied with NAD, the activity of NAD-dependent aldehyde dehydrogenase was higher in the ethanol-fed rats than in the linked controls. The activity of glutamate dehydrogenase remained unchanged, however. The data suggest that elevated blood acetaldehyde resulting from enhanced ethanol metabolism or decreased disposition may impair mitochondrial functions, including the capacity to oxidize acetaldehyde. This, in turn, will elevate the acetaldehyde concentration in the blood even further, which may then perpetuate injury not only in the liver but possibly also in the heart and brain.

6841 EFFECTS OF CHRONIC ETHANOL ADMINISTRATION IN THE RAT: RELATIVE DEPENDENCY ON DIETARY LIPIDS -- I. INDUCTION OF HEPATIC DRUG-METABOLIZING ENZYMES IN VITRO.

(E.) Joly, J. G.; Hetu, C. (Hopital Saint-Luc, 1058 St. Denis St., Montreal, Quebec, Canada H2X-3J4). *Biochem. Pharmacol.* 24(16):1475-1480, 1975.

The importance of dietary lipid, daily ethanol intake, and undernutrition on the effects of ethanol on drug-metabolizing activities *in vitro* was studied in female Sprague-Dawley rats. The animals were pair-fed for 5 to 7 wk on high- or low-fat diets containing 5% or 6% (w/v) ethanol, or were fed *ad libitum* or were given restricted hypocaloric diets for 21 and 28 days, resp. The livers were then removed and the liver microsomes were tested *in vitro* for microsomal demethylation activity, NADPH-cytochrome c reductase, MEOS, protein, and cytochrome P-450. Ethanol given as a 5% solution with high amounts of dietary fat increased cytochrome P-450, the activities of NADPH-cytochrome P-450 reductase, benzphetamine demethylation, aniline hydroxylation, and MEOS. When 5% ethanol was given with a low fat diet, the increases in cytochrome P-450 and P-450 reductase were reduced, but the other enzyme activities were increased to the same extent as seen with the high fat diet. When ethanol was administered as a 6% solution with a low fat diet, caloric deficiency was observed and there was no significant induction of any enzymic parameter except aniline hydroxylation. When 6% ethanol was given with a high fat diet, however, cytochrome P-450 and P-450 reductase, but not MEOS, were increased despite the caloric deficiency. Ingestion of 6% ethanol with the high fat diet resulted in a negligible weight gain. In the animals fed the hypocaloric diet *ad libitum*, growth was impaired by 66% and the liver cytochrome P-450 level was increased, but there were no other significant changes; the caloric intake in these animals was similar to that in the 5% ethanol-high fat and 6% ethanol-low fat groups. In the animals fed the restricted hypocaloric diet, significant increases in cytochrome P-450, NADPH-cytochrome P-450 reductase, and benzphetamine demethylation were observed, and aniline hydroxylation was nonsignificantly elevated; the caloric intake in these animals was similar to that in the 6% ethanol-high fat group. The data indicate that the induction of drug-metabolizing enzymes by ethanol is partially dependent on dietary lipids, as well as on the amounts of ethanol ingested and on the nutritional status of the animal.

6842 ALCOHOL-INDUCED TESTICULAR ATROPHY: AN EXPERIMENTAL MODEL FOR HYPOGONADISM OCCURRING IN CHRONIC ALCOHOLIC MEN.

(E.) Van Thiel, D. H.; Gavaler, J. S.; Lester, R.; Goodman, M. D. (Univ. Pittsburgh Sch. Medicine, Pittsburgh, Pa. 15261). *Gastroenterology* 69(2):326-332, 1975.

The effect of chronic alcohol ingestion (*via* a liquid diet in which ethanol accounted for 36% of the total calories) on testicular growth, development and function was studied in male Wistar rats aged 20 days at the start of the experiment. The ethanol-fed animals and a group of pair-fed controls were killed at 61 days of age and the liver, testes, prostate gland, seminal vesicles and pituitary glands were weighed and examined histologically. The plasma testosterone and serum total bilirubin, alkaline phosphatase, and glutamic pyruvic transaminase levels were also determined. *Ad libitum*-fed controls gained weight steadily until 60 days of age, and the testes, prostate and seminal vesicles increased in mass until reaching adult size and histologic appearance at 40 days of age; the plasma testosterone concentrations reached adult levels at 40 to 50 days. At death, the ethanol-fed rats showed a significant reduction in testicular mass relative to body weight compared to their pair-fed controls, although the absolute testicular mass of the latter was reduced compared with that of the *ad libitum*-fed controls. The reduction in testicular mass in the alcohol-fed rats was due primarily to a reduction in the mean seminiferous tubular diameter and the amount of germinal epithelium within the tubules. Leydig cell function was also disturbed in the ethanol-treated animals; there was a significant reduction in the ventral prostate and seminal vesicle mass relative to body mass, and the histologic appearance of the seminal vesicles and ventral prostate was one of complete androgen deprivation. In addition, the plasma testosterone concentrations in the ethanol-fed rats were significantly reduced in comparison with the pair-fed and *ad libitum*-fed controls. However, the pituitaries of the three groups showed no apparent histologic differences. Despite the fact that the body mass was significantly reduced in the ethanol-fed rats compared with the pair-fed controls, the liver weight and ratio of liver mass to body mass were increased in the former as compared with the latter. Although fatty metamorphosis was present in the livers of the ethanol-fed rats, there was no histologic evidence of acute inflammation, necrosis or portal fibrosis, and liver function tests were within normal limits. The data support the view that ethanol is a primary testicular toxin.

6843 EFFECT OF LIFETIME EXPOSURE TO AFLATOXIN B_1 IN RATS.

(E.) Ward, J. M.; Sontag, J. M.; Weisburger, E. K.; Brown, C. A. (Natl. Cancer Inst., Bethesda, Maryland 20014). *J. Natl. Cancer Inst.* 55(1):107-113, 1975.

The effects on rats of exposure to aflatoxin B_1 (AFB_1) through transplacental and milk metabolites, followed by lifelong dietary exposure, was studied. Pregnant F344 rats were fed a diet containing 2 ppm AFB_1 throughout gestation and lactation, and the waned offspring were fed the same diet until they died. For comparison, this diet was also administered to another group of rats beginning at age six or seven weeks. The survival of male rats was significantly shorter than that of females of both groups, i.e., 45.6 *versus* 61.6 weeks in the group exposed from conception and 50.2 *versus* 63.1 weeks in the group exposed from six or seven weeks. The major causes of death were rupture of a hemorrhagic liver tumor and hemoperitoneum or pulmonary metastases with or without hemothorax. Histologically, the hemorrhagic liver tumors were hemangiosarcomas composed of poorly differentiated cells resembling endothelial cells. Nodules of hyperplasic liver cells sometimes became quite large (> 1.5 cm), and two were successfully transplanted. The hemangiosarcomas rapidly induced pulmonary metastatses upon s.c. transplantation into weanling and young adult rats, but did not elevate serum α-fetoprotein levels in recipients. After 20 serial passages, the morphology of the tumor resembled that of the original primary liver tumor. Colon tumors also appeared in more than 20% of the rats exposed *in utero* or given AFB_1 at six or seven weeks. These tumors were primarily polyploid neoplasms in the descending colon. A few rats had tumors of the kidney, oral cavity, and hematopoietic system. These results indicate that AFB_1 should be considered a colonic as well as a hepatic carcinogen.

6844 DIVERSE EFFECTS OF ANTIOXIDANTS ON CARBON TETRACHLORIDE HEPATOTOXICITY.

(E.) De Ferreyra, E. C.; Castro, J. A.; Gomez, M. I. D.; D'Acosta, N.; De Castro, C. R.; De Fenos, O. M. (Laboratorio de Quimica Bio-Toxicologia, CITEFA, Zufriategui y Varela, Villa Martelli, Pica. de Buenos Aires, Argentina). *Toxicol. Appl. Pharmacol.* 32(3):504-512, 1975.

The diverse effects of *in vitro* antioxidants on carbon tetrachloride hepatotoxicity were investigated in Sprague-Dawley rats. The prior treatment of animals with oil solution of α-tocopherol acetate did not have an effect on CCl_4 concentrations in liver when the hepatotoxin was given p.o. or i.p. and determinations were performed at intervals up to 3 hr. Similarly, the content of CCl_4 in livers of rats pretreated with a saline solution of 25 mg/kg promethazine was not significantly different from that of the untreated animals given CCl_4 i.p. Oil suspensions of 600 mg/kg *N*,*N*'-diphenyl-*p*-phenylenediamine were not able to modify the amount of CCl_4 reaching the liver 1, 3, or 6 hr after oral administration of CCl_4. Water suspensions were able to significantly modify the 1-hr concentrations in liver of CCl_4 given p.o. Significant decreases were found in CCl_4 concentrations in the liver when water suspensions of *N*,*N*'-diphenyl-*p*-phenylenediamine were used and CCl_4 was given i.p. The effect was observed at 3 hr but was more pronounced at 6 hr. Oil suspensions did not produce significant differences in CCl_4 concentrations in liver at 1 or 3 hr in rats given CCl_4 i.p. α-Tocopherol acetate did not modify the extent of the irreversible binding of ^{14}C to microsomal lipids, but *N*,*N*'-diphenyl-*p*-phenylenediamine decreased it significantly. α-Tocopherol acetate, *N*,*N*'-diphenyl-*p*-phenylenediamine given either as oil or water suspensions, as well as promethazine, were not able to prevent the CCl_4-induced lipid peroxidation at 40 min or 3 hr after CCl_4 administration. These results weaken the value of previous findings with antioxidants which were used to support the lipid peroxidation theory of CCl_4 hepatotoxicity.

6845 EFFECT OF 17α-ETHINYLESTRADIOL ON BILIARY EXCRETION OF BILE ACIDS.

(E.) Watanabe, H. (Drug Res. Lab., Dep. Natl. Health Welfare, Ottawa, Canada). *Biochim. Biophys. Acta* 399(1):79-84, 1975.

The effects of 17α-ethinylestradiol on bile acid excretion and metabolism were studied in female Wistar rats. The common bile duct was cannulated, and for 3 days prior to bile collection all animals were fed cholestyramine (3% added to a ground fox cube diet). 17α-Ethinylestradiol in 10% ethanolic saline was administered by oral intubation daily for 4 days at a dose level of 1, 10, 25, 50, 100 or 250 μg; controls received ethanolic saline. In another group of cholestyramine-treated and untreated rats, 17α-ethinylestradiol was administrred for 1 to 10 days at a dose level of 500 μg. Eighteen hr after the last dose of steroid, bile samples were collected over a 3-hr period. The bile salts were extracted, hydrolyzed, methylated, and analyzed by gas-liquid chromatography. The ratio of cholate to chenodeoxycholate was progressively diminished by estrogen treatment up to 25 μg. At dose levels between 50 and 250 μg, there were no further increases in the chenodeoxycholate levels nor further declines in the cholate:chenodeoxycholate ratio. There was a tendency towards a decrease in cholate levels in this dose range, the reduction also being apparent in animals treated with 500 μg of estrogen. Prolonged treatment with 500 μg/day of 17α-ethinylestradiol produced a progressive reduction in the excretory rate of both bile acids in cholestyramine-treated and untreated animals. The effects of various other estrogens were similar to those of 17α-ethinylestradiol while various progestins were without effect. The responses were similar following p.o. and s.c. treatment. The results indicate that 17α-ethinylestradiol in low doses stimulates chenodeoxycholate excretion, whereas in high doses it reduces cholate excretion.

6846 CAERULEIN EFFECT ON THE BILIARY EXCRETION OF COLORANTS.

(E.) Angelucci, L.; Linari, G.; Baldieri, M. (Inst. Pharmacol. Pharmacognosy, Univ. Rome, Italy). *Pharmacol. Res. Commun.* 7(4): 311-322, 1975.

The effects of cerulein (15-50 ng/kg/min, i.v.) on the biliary excretion and plasma concentration of BSP (200-600 or 1000 μg/kg/min, i.v.) and rose bengal (RB, 100-175 μg/kg/min, i.v.) were studied in lightly anesthetized white Leghorn-Rhode Island chickens. In some experiments both hepatic bile ducts were cannulated so that the enterohepatic circulation of bile salts was totally interrupted; in other experiments, only the left duct was cannulated. Also, in some experiments, Na taurocholate was given by continuous i.v. infusion (200 μg/kg/min) throughout. Cerulein stimulated bile flow during BSP (200-600 μg/kg/min) administration in the absence of an enterohepatic circulation of bile salts. Bile salt output and biliary BSP output were unaffected. When Na taurocholate was infused with BSP under similar conditions, cerulein stimulated choleresis and increased the output and concentration of bile salts. The biliary excretion of BSP was unaffected, as were plasma levels of the colorant. In animals receiving BSP at a rate of 1000 μg/kg/min, however, cerulein did stimulate the biliary excretion of the colorant and also affected its plasma levels. During BSP administration (500 μg/kg/min) in the presence of a partial enterohepatic circulation of bile salts, cerulein (25 ng/kg/min) produced an intense total choleresis, an increase in bile salts output and concentration, and increases in the biliary excretion and plasma levels of BSP. Similar results were found during the administration of RB. The results indicate that cerulein increased the biliary excretion of BSP and RB only when the colorants were infused at rates higher than the maximum liver transport capacity (Tm) and when some bile salt was available for secretion. It appears that cerulein, by increasing choleresis, reduces the limiting factor to the excretion of colorant into bile under liver Tm conditions, i.e., its concentration in the canalicular bile.

6847 MORPHOLOGICAL ASPECTS OF TREATING PATIENTS WITH CHOLECYSTITIS WITH CHENODEOXYCHOLIC ACID.

(Ger.) Leuschner, U. (Cent. Intern. Med., Johann Wolfgang Goethe Univ., Frankfurt/Main, Germany). *Z. Gastroenterol.* 13:309-313, 1975.

To determine whether therapeutic doses of chenodeoxycholic acid are hepatotoxic, 20 mg/kg doses were administered p.o to rats for 5 to 60 days. The animals were then sacrificed, and the entire gastrointestinal tract was examined by light and electron microscopy; findings were compared to those from untreated controls. In two of the five rats examined, bile capillaries were dilated and contained lipid-like material; the villi had completely disappeared after 20 days of treatment. After 60 days of treatment, light vacuoles were present in hepatocyte cytoplasm along intercellular spaces and right below the outer cell membranes. Digitate or cystic dilatations of the intercellular space were detected which, in some cases, resembled bile capillaries. Since the contents of cytoplasmic vacuoles resembled those of the intercellular cysts, it is suggested that these structures are inclusion vacuoles arising from invagination of the outer cell membrane and that they contain substances normally secreted in the bile. These findings demonstrate that doses of chenodeoxycholic acid, similar to those given to patients with cholesterol gallstones, are hepatotoxic to rats although chenodeoxycholic acid and its derivative, lithocholic acid, may be readily detoxified by 6β-hydroxylation. Abnormalities found in the jejunal epithelium consisted of deposits of fat in submembranous vesicles and supranuclear deposits of highly osmiophilic, lipid-like substances. Many cells were swollen, and microvilli were broader and coarser than in untreated controls. In rats given chenodeoxycholic acid for 60 days, a decrease occurred in the number of villi and in their length, and the terminal reticulum was dispersed in some cells found in the ileum. These changes might be a manifestation of disorders in the electrolyte and water balance.

6848 TOXICITY OF CHENODEOXYCHOLIC ACID IN THE RHESUS MONKEY.

(E.) Dyrszka, H.; Chen, T.; Salen, G.; Mosbach, E. H. (New Jersey Medical Sch., Newark, N.J.). *Gastroenterology* 69(2):333-337, 1975.

To determine the mechanism of toxicity of chenodeoxycholic acid, the bile acid was administered daily (10, 40 or 100 mg/kg, p.o.) for 1 mo to male and female rhesus monkeys; control animals were given placebo.

The animals were killed after 33 days of bile acid administration or 9 days after the cessation of treatment. Changes in the blood and serum values, biliary lipids, and liver tissue were recorded. The serum leucine aminopeptidase values increased in proportion to the dose of chenodeoxycholic acid administered. The total blood count, SGOT, serum bilirubin, serum total protein and albumin, serum cholesterol, blood urea nitrogen, creatinine, electrolytes and blood glucose levels remained within normal limits in all treatment groups. Bile acid administration caused a marked decrease in the proportion of cholic acid and deoxycholic acid in the bile, and chenodeoxycholic acid became the major component of the biliary acids. The proportion of lithocholic acid also increased seven- to ten-fold; in the 40 and 100 mg/kg groups it exceeded the amount of cholic acid and deoxycholic acid. There were no significant changes in the biliary phospholipid or cholesterol concentrations. The bile acid composition had markedly improved in the animals killed 9 days after cessation of bile acid treatment. Liver biopsies obtained before treatment and at necropsy showed no significant histological changes. The data indicate that the hepatic toxicity which developed following the administration of chenodeoxycholic acid may result from an inability to metabolize chenodeoxycholic acid itself or its bacterial metabolite, lithocholic acid.

6849 CIRRHOSIS OF CHOLINE DEFICIENCY IN THE RHESUS MONKEY. POSSIBLE ROLE OF DIETARY CHOLESTEROL.

(E.) Patek, A. J., Jr.; Bowry, S.; Hayes, K. C. (Veteran's Administration Hosp., Boston, Mass. 02130). *Proc. Soc. Exp. Biol. Med.* 148(2):370-374, 1975.

The production of cirrhosis by a choline-deficient diet lacking peanut meal and cholesterol was studied in adult rhesus monkeys. The monkeys were fed a basic choline-deficient diet, the same diet with added choline, or commercial chow. After 14 months, the animals which had been maintained on the basic choline-deficient diet were divided into two groups; one group received the original diet, and the second received a cholesterol supplement comprising 2% of the diet. The experiment was continued for a total of 31 months. Venous blood samples and needle biopsies of the liver were examined at 3-month intervals. Growth rates were similar in all groups, and the blood chemistries were normal except in two animals which developed cirrhosis, and in the protein- and choline-deficient animals; the latter developed a moderate anemia and hypoalbuminemia. Patch alopecia developed in several animals fed the cholesterol supplement. The livers of the animals fed the choline-deficient diet and the choline-supplemented diet showed slight fatty changes, fine vacuolation, and ballooning of the hepatocytes. A sharp increase in fat was seen in the livers of the animals fed supplemental cholesterol. Cirrhosis developed in one animal after 26 months on the choline-deficient diet and in another monkey after 2 months on the cholesterol-supplemented diet. Electron microscopy showed depletion of cytoplasmic constituents in the animals fed the low-protein diets, but no other changes. The data indicate that the rhesus monkey can develop choline-deficiency cirrhosis, although it is less susceptible than the rat. The addition of cholesterol to the diet appears to exert an hepatotoxic effect.

6850 ULTRASTRUCTURAL STUDIES OF THE HEPATOCYTES AFTER CHRONIC EXPOSURE TO LOW LEVELS OF HALOTHANE.

(E.) Chang, L. W.; Dudley, A. W.; Lee, J. K.; Katz, J. (Dept. Pathology, Univ Wisconsin, Madison, Wis. 53706). *Exp. Mol. Pathol.* 23(1):35-42, 1975.

Electron microscopy (EM) was used to study the pathological effects on the liver of long-term, chronic exposure to low levels of halothane. Adult Sprague-Dawley rats of both sexes were used. Halothane exposures were 10 ppm, 8 hr/day, five days/wk for 8 wk and 500 ppm, 8 hr/day, five days/wk for 4 wk. EM study of the low dose liver tissue showed an increase in matrical density of the mitochondria and some C-shaped transformation. There was also an accumulation of floccular, electron-dense material around the rough endoplasmic reticulum. At the higher dose, severe dilation of bile canaliculi was observed with a flattening and loss of microvilli; extrusion of cellular debris with peribiliary accumulation of electron-dense bodies, presumed to be lysosomes, was also evident. Occasionally, large, membrane-limited floccular bodies containing remnants of cytoplasmic material (focal cytoplasmic degradation) were observed. Halothane was concluded to have a direct hepatotoxic effect.

6851 METHIONINE-INDUCED HEPATIC COMA IN DOGS.

(E.) Merino, G. E.; Jetzer, T.; Doizaki, W. M. D.; Najarian, J. S. (Univ. Minnesota Hosp., Minneapolis, Minn.). *Am. J. Surg.* 130:41-46, 1975.

The relation between p.o. methionine doses and blood ammonia and methanethiol levels was analyzed. Mongrel dogs (19) were given portacaval shunts and fed a daily diet containing 25 g of protein and 40 g of lipids. Fasting ammonia level was measured daily before feeding, and liver enzyme and electrolyte levels were measured every third day. Of the dogs, 11 were fed methionine (25 g every 4 hr) *via* nasogastric tube as a 50% aqueous suspension until the animal became comatose. The remaining 8 plus 8 nonshunted dogs served as controls. Ammonia values were monitored every 4 hr during methionine feeding, and blood methionine levels were determined when coma ensued. None of the dogs showed encephalopathy up to the 21st postoperative day, regardless of ammonia level. Methionine feeding was begun when fasting ammonia levels reached 250 to 500 μg/100 ml in three dogs, at 500 to 1000 μg/100 ml in two, at 1000 to 1250 μg/100 ml in three, and at 1250 to 1500 μg/100 ml in three. Coma developed in two dogs after five boluses of methionine, in two after four boluses, in three after three boluses, in two after two boluses, and in one after one bolus. Of 10 episodes of deep or very deep coma, three were fatal, and seven other abnormal neurologic conditions were classified as subcoma. Average fasting ammonia levels remained stable around 450 μg/100 ml, and gradually increased to 750 μg/100 ml over 10 days. SGOT and serum alkaline phosphatase levels rose slowly over the 10 days. Lower methionine doses (25 g) could trigger coma in dogs with high ammonia levels (over 1250 μg/100 ml) and doses up to 125 g were needed to induce coma when ammonia levels were under 500 μg/100 ml. In the four dogs that died during coma, the pH and electrolyte values showed metabolic acidosis, hypoxemia, hypoglycemia, hypokalemia, thrombocytopenia, hemolysis, and intravascular coagulation during the terminal stages. Methanethiol blood levels increased proportional to the dose given. A 3-fold increase in ammonia level increased the comatogenicity of methanethiol 100-fold. A dog with an ammonia level of 300 μg/ml required 100 times the methanthiol level of one with an ammonia level of 1200 μg/ml to become comatose. Controls showed no evidence of encephalopathy even after massive doses. Infusion of ammonium ions in controls showed concentrations of 5500 and 9000 mg/100 ml blood corresponded to complete coma. In controls, convulsions and coma were induced by 3 to 5 ml 1:40 methanethiol i.v. in 0.1 M NaOH. After injection of 1 ml methanethiol, 1/5 of the previously determined comatogenic dose of ammonia induced encephalopathy. It is concluded oral methionine is comatogenic in dogs with portacaval shunts and with elevated blood ammonia levels.

6852 SIGNIFICANCE OF LIVER CANALICULAR CHANGES AFTER EXPERIMENTAL BILE DUCT LIGATION. *(E.)*

De Vos, R.; De Wolf-Peeters, C.; Desmet, V.; Bianchi, L.; Rohr, H. P. (Departement Medische Navorsing, Laboratorium voor Histochemie en Cytochemie, Academisch Ziekenhuis St. Raphael, Katholicke Universiteit Leuven, B-300 Leuven, Belgium). *Exp. Mol. Path.* 23(1):12-34, 1975.

A study was undertaken to analyze the canalicular morphological and histochemical changes in the liver after bile duct ligation and to compare these findings with those present in canaliculi found during the perinatal period. Twenty-one adult male Wistar R rats were subjected to bile duct ligation (BDL). The time interval between surgical intervention and sacrifice was 1, 2, 3, 4, 9, 20 or 40 days. One day after BDL there was an immediate, positive alkaline phosphatase reaction in all canaliculi; this activity was limited to the luminal contents; it remained high during the entire experimental period. EM study revealed progressively increasing dilation of the canaliculi, loss of microvilli and invagination and interdigitation of the hepatocellular plasma membranes. There was pericanalicular ectoplasm surrounding most of these canalicular structures, which were strongly widened, swollen and edematous. Morphometry was used to characterize the diffuse canalicular types. The frequency of the four prototypes of canalicular structures varied depending on the duration of the BDL. These four types were briefly described. Canaliculi found in the perinatal liver corresponded to type 3 (inactive) canaliculi of BDL ducts. The data point to an evolution in the morphological appearance of the biliary pole of the hepatocytes after BDL as well as the newly formed canalicular structures.

6853 REVERSIBILITY OF MORPHOLOGICAL CHANGES IN THE LIVER FOLLOWING EXPERIMENTAL BILE DUCT OBSTRUCTION. *(Ger.)*

Schweizer, P.; Reifferscheid, P. (Chirurgische Universitatsklinik, 74 Tubingen, Calwer Strasse 7, Germany). *Z. Kinderchir.* 15(2): 174-187, 1974.

The common bile duct was ligated and excised between the duodenum and the outlet of the cystic duct in two-day-old female swine. Bile flow was then restored four, six, or eight weeks after surgery by performing a cholecystoduodenostomy. Controls consisted of six sham-operated swine. Morphometric analysis of liver sections, determinations of serum bilirubin, serum enzymes (SGOT, SGPT, γ-glutamate transaminase, leucine aminopeptidase, and alkaline phosphatase), and the Quick test, and measurements of portal venous pressure revealed that changes induced by bile duct ligation were reversible if bile flow was restored four to five weeks after ligation. If drainage operations were performed later, the progress of fibrosis could no longer be arrested. After fibrous tissue extended throughout the lobules of the liver, increases in portal venous pressure became irreversible. The transition from reversible to irreversible changes in the liver could be established by the ratio of glutamate transaminase/leucine aminopeptidase: this ratio was 1 in normal animals and larger in swine with changes in the hepatic lobules. Much less fibrosis and less severe portal hypertension were found in swine with extensive adhesions between the small intestine and the porta hepatis than in swine who did not develop adhesions. Biochemical findings normalized four weeks after bile duct ligation in swine with such adhesions. It is suggested that this is due to drainage of bile through lymphatic anastomoses between the hepatoduodenal ligament and the small intestine. This hypothesis is supported by the appearance of spots of bile on the cut surface when adhesions were separated.

6854 EFFECT OF PORTACAVAL SHUNT AND ARTERIALIZATION OF THE LIVER ON BILE ACID METABOLISM. *(E.)*

Horak, W.; Gangl, A.; Funovics, J.; Grabner, G. (Dept. Gastroenterology, Univ. Vienna, Vienna, Austria). *Gastroenterology* 69(2):338-341, 1975.

The clearance of endogenous bile acids which normally reach the liver *via* the portal vein was studied in mongrel dogs subjected to portacaval end-to-side shunt with and without arterialization of the hepatic portal venous bed. Blood was obtained from the portal and peripheral veins before surgery, postoperatively, and at two-wk intervals thereafter for determination of bile acids and routine laboratory tests. Ten wk after surgery, liver biopsies were obtained and the dogs were killed and the livers weighed. Portacaval shunting caused a 75% decrease in the total hepatic blood flow; this was prevented by arterialization of the shunted liver. Body weight remained constant in all animals, but the liver weight was significantly reduced in the animals subjected to portacaval shunt. The liver mass in the arterialized dogs did not differ significantly from that in the normal controls or in the animals subjected to portacaval shunt only. Serum bilirubin levels remained constant in all animals. However, SGOT was increased in the shunted but not in the arterialized animals, and the serum ammonia and bile acid concentrations were increased postoperatively in both groups, but to a significantly greater extent in the shunted animals. Total serum cholesterol declined significantly in both groups after surgery. Clearance was significantly reduced in the shunted dogs, but remained at normal values in the arterialized dogs. There was a linear correlation between hepatic bile acid clearance and total liver blood flow. The data indicate that portacaval shunt combined with arterialization of the liver is associated with less severe histological and biochemical problems than portacaval shunt alone.

6855 ACUTE BIOCHEMICAL AND HISTOLOGICAL EFFECTS OF PORTACAVAL SHUNT IN THE NORMAL RAT. *(E.)*

Meyers, O. L.; Hickman, R.; Keraan, M.; Engelbrecht, G. H. C.; Webber, B. L.; Terblanche, J. (Dep. Medicine, Univ. Cape Town, South Africa). *S. Afr. Med. J.* 49(26):1048-1050, 1975.

The early course of changes in total serum protein and evidence of liver damage were studied after portacaval shunt. Five groups of 12 rats each were given end-to-side portacaval shunts or were sham operated in a random distribution. Four groups were killed at 6, 24, 48, and 96 hr after surgery and exsanguinated. A final group of six was killed at 24 hr without exsanguination. Liver biopsies were studied by light microscopy and blood samples were subjected to protein electrophoresis and analyzed for antibacterial lipopolysaccharide antibodies and aspartate aminotransferase. Mean albumin levels were similar in shunt and control rats up to 72 hr; at 96 hr levels were significantly higher in the controls. Mean albumin levels fell during the four days in both groups. In the α-globulin fraction in controls, $\alpha_1$and α_2 levels rose, but in shunt rats α_1 levels only rose. The greatest difference between the two groups was in the β-globulin fraction, which rose significantly in 24 hr in the controls, but fell in the shunt rats. Neither group showed a significant change in γ-globulin levels. There was no rise in antibacterial lipopolysaccharide bodies in any animals. Aspartate aminotransferase showed a nine-fold increase in shunted rats from 139.1 Karmen U preoperatively. Controls showed a two-fold increase. Values returned to normal in all rats after 72-96 hr. There was no difference between exsanguinated and nonexsanguinated rats. Biopsies from shunted rats six and 24 hr after surgery showed marked hepatic necrosis. Aspartate aminotransferase levels were significantly elevated. At 48 and 96 hr these areas were undergoing phagocytosis and regeneration; aspartate aminotransferase levels returned to normal. There was minimal collapse of hepatic architecture by day five. It is concluded that portacaval shunt results in hepatocellular damage which returns to normal within 48 hr; shunted animals maintain albumin levels better than sham-operated controls.

6856 CHOLESTEROL AND BILE ACID METABOLISM AFTER RESECTION OF THE SMALL INTESTINE. *(Ger.)*

Weis, H. J.; Dietschy, J. M.; Baas, E. V. (I. Med. Klinik Univ. Mainz, Germany). *Verh. Dtsch. Ges. Inn. Med.* 80:419-421, 1974.

Surgery was performed on the small intestine in three groups of 10 rats each: (1) resection of the distal half of the small intestine and anastomosis of the ends; (2) resection of the proximal half of the small intestine and anastomosis of the ends; and (3) sham surgery in which the ileum was cut and anastomosed. The rats were then fed 15 g/day of rat food for seven weeks. Jejunectomized rats weighed the same as controls, while ileectomized rats weighed significantly less. This decrease in body weight can be accounted for by excretion of fat in the stools which was twice as high in ileectomized rats as in the other two groups. In all three groups, serum cholesterol levels decreased slightly between days three and nine after surgery and then reached a plateau above the initial values. Cholesterol synthesis in the liver and intestine, studied by incubation of tissue slices with 2-^{14}C-acetate, remained unchanged after jejunectomy but tripled after ileectomy. Surgery had no effect on CO_2 and fatty acid production in the liver. After jejunectomy, the rate of cholesterol synthesis was significantly higher in the proximal ileum than in controls, while in ileectomized rats cholesterol was synthesized at three times the control value in the jejunum. If the total weight of the small intestine is taken into account in determining cholesterol synthesis, the small intestine of rats in groups (1) and (2) synthesized almost the same amount of cholesterol as that of the controls. Determinations of sterols in the stools revealed that ileectomized rats excreted significantly more neutral and acid sterols than the other two groups of animals. This was also demonstrated indirectly by the decreased taurocholic acid pool and increased turnover rate in ileectomized rats. It is concluded that in ileectomized rats increased excretion of neutral and acid sterols is compensated for by increased hepatic cholesterol synthesis. This compensatory mechanism could also occur in man and account for failure of ileal bypass surgery to reduce high serum cholesterol levels.

6857 FORMS OF PHYSIOLOGICAL LIVER REGENERATION IN ANIMALS UNDER PROLONGED HYPERBARIC CONDITIONS. *(Rus.)*

Dashevskii, B. S.; Kostkin, V. B. (I. M. Sechenov Inst. Evol. Physiol. Biochem., Leningrad, USSR). *Dokl. Akad. Nauk SSSR* 222(1): 254-256, 1975.

The effect of prolonged hyperbary in a helium-oxygen atmosphere on physiological regeneration of the liver was studied in 42 adult rabbits (3 to 3.5 kg). Basic experiments were performed on 16 rabbits in a high-pressure chamber (35 kg/cm^2) in an artificially regenerated helium-oxygen atmosphere (with partial pressure of oxygen 0.31-0.36 kg/cm^2) and at the temperature of 29 to 30 C. After gradual decompression of the high-pressure chamber, the experimental animals were killed, and small portions of their livers were removed. For determinations of the number of mitoses and binuclear cells, at least 3,000 hepatocytes were used. Mononuclear hepatocytes were examined photometrically. The frequency of mitosis under hyperbaric conditions increased by 35% after 12 hr, but decreased by 42% (with respect to the initial value) after 10 to 17 days, and by 48% after 30 days. The degree of polyploid of hepatocytes (the ratio of tetraploid/diploid cells) decreased steadily with the time of exposure to the high pressure (2.2 initially; 0.50 after 12 hr; 0.45 after 30 days). Finally, the measuements of the population of binuclear

cells showed that this type of cell constantly in-
creased with the time of exposure to high pressure
(9% initially; 18% after 12 hr; 24% after 30 days).
Considering that physiological regeneration should
be accompanied by enhanced cellular proliferation
(increased frequency of mitosis), enhanced poly-
ploid, and increased population of binuclear cells,
the results showed that only the last one of the
three indicated prerequisites was satisfied. On the
basis of this fact, it must be concluded that the
possibility of physiological regeneration of the
liver under prolonged hyperbary is substantially
diminished.

5858 THE RELATIONSHIP OF RETICULOENDOTHELIAL DYSFUNCTION AND ENDOTOXEMIA TO SURVIVAL AFTER IEPATIC ISCHEMIA INJURY IN THE BABOON.

(E.) Di Luzio,
I. R.; Olcay, I.; Holper, K.; Drapanas, T.; Trejo, R.
(Tulane Univ. Sch. Medicine, New Orleans, La.). *Cir-
ulatory Shock* 2(2):77-89, 1975.

'he effects of prolonged ischemia on survival, hemo-
ynamics, and hepatocyte and Kupffer cell function were
nvestigated in the subhuman primate. Of 34 baboons
Papio papio), 19 were subjected to 60 or 90 min of
iver ischemia by total vascular occlusion, 9 served
s sham-operated controls, and 6 underwent portacaval
hunting and were subdivided into control and experi-
ental groups. Phagocytic activity of the reticuloen-
othelial system, circulating blood volume, and hepatic
lood flow were determined as well as arterial pH and
lood gases, total plasma bilirubin, glutamic oxalacetic
ransaminase, lactic dehydrogenase, ornithine carbamyl
ransferase activities, and plasma BSP concentration.
eterminations were made before occlusion, and at 3,
4, and 48 hr after restoration of flow. Endotoxin
eterminations were made before, during, and after oc-
lusion. Occlusion for 90 min resulted in 45% survi-
al. Survivors recovered in a few days; the rest died
t a mean of 43 hr. Mean arterial pressure decreased
1% within 5 min of occlusion and maintained that level
ntil restoration in the survivors. In the nonsurvivors,
ressure decreased by 54%. Recovery of pressure was
een in both groups after restoration. BSP retention
as significantly higher in the experimental group (3.27
fter 24 hr) than in controls (0.37). When reticulo-
ndothelial function was tested with ^{131}I-test lipid
mulsion, the survivors had a slightly increased i.v.
/2 time at 3 hr, and increased 120% (to 41 min) at 24
r. The nonsurvivors had an i.v. 1/2 time of 141 min at
 hr, significantly higher than that of the survivors.
ean hepatic blood flow decreased 50 to 60% in the 3 hr
ostocclusion period but returned to normal (21.2 ml/
n/kg) at 24 hr in both survivors and nonsurvivors.
ood volume decreased significantly from normal (98.1
/kg) three hr after occlusion. Further decreases of
% and 48% occurred in survivors and nonsurvivors,
sp., at 24 hr, these values being significantly dif-
rent. Plasma samples from either portal vein and the
moral artery were negative for endotoxin prior to
clusion, but 60% of the animals were positive after
 min of ischemia. After an additional 30 min, all
re positive. There was no correlation between inci-
nce and magnitude of endotoxemia and survival or
nsurvival. In three portacaval shunt animals that
derwent 90 min of ischemia and died, persistent endotoxemia was observed. Peak levels appeared between 6 and 12 hr and ranged from 1.6 to 3.2 mg/ml. Levels declined to 0.5 mg/ml by 24 hr. Phagocytic activity was depressed; the half times at 3 and 24 hr were prolonged 2.4- and 3.8-fold, resp. Depression of reticuloendothelial function and endotoxemia were associated with nonsurvivors, while function was normal in one survivor. One sham-operated animal died after exhibiting depressed phagocytic activity and associated endotoxin increase. It is concluded that 60-90 min of hepatic ischemia was associated with 45% survival and that the degree of reticuloendothelial impairment, but not liver function tests, correlated with survival.

6859 METABOLISM IN THE LIVER DURING CHOLESTASIS.

(Ger.) Llersch, M.; Hesse, W. (Med. Univ. Klinik, Heidelberg, Germany). *Verh. Dtsch. Ges. Inn. Med.* 80:429-432, 1974.

To study the effect of cholestasis and dihydroxy bile acids on liver metabolism, experiments were performed on isolated, perfused livers from fasting male Sprague-Dawley rats which had undergone bile duct ligation 7 days previously. Livers from intact rats served as controls. Bile duct ligation or addition of free or taurine-conjugated chenodeoxycholic acid (0.25 mM) had no effect on endogenous gluconeogenesis, urea synthesis, or the synthesis of lactate and ammonium chloride. No significant differences in the contents of adenine nucleotides, lactate, pyruvate, 3-hydroxybutyrate, acetoacetate, uridine diphosphate-glucose, or glucose were found in livers from bile-duct-ligated rats and intact controls. The glycogen content of livers from the bile-duct-ligated rats was only 50% of the control value, but this can be explained by a reduced food intake in these rats. Since early cholestasis, a decrease in ATP, and pronounced morphological changes have been reported to occur during perfusion of livers from female Wistar rats with chenodeoxycholic acid, experiments were also performed on these animals. In contrast to reports in the literature, chenodeoxycholic acid had a choleretic action and no changes occurred in the ATP content or in hepatic biosynthesis. Perfusion experiments on livers from normal and bile-duct-ligated rats with oleic acid, however, showed that in cholestatic livers ketone body production from oleic acid was decreased to 66% and endogenous production to less than 50% of normal values. Taurochenodeoxycholic acid further reduced ketone body production from oleate to 45% of normal values, but deoxycholic and free and conjugated chenodeoxycholic acid appeared to have no direct effect on normal liver or livers in which the bile ducts were ligated during perfusion, even though bile-duct-ligated livers took up about 50% of the bile acids from the perfusion medium after bile flow ceased. These findings suggest that cholestasis does not have a direct toxic effect on metabolism in the hepatic mitochondria.

6860 EFFECT OF GASTROINTESTINAL FLORA ON BILE ACID METABOLISM IN THE RAT.

(Fr.) Sacquet, E.; Van Heijenoort, Y.; Riottot, M.; Leprince, C. (Laboratory Germ-Free Animals, Gif-sur-Yvette, France). *Biochim. Biophys. Acta* 380(1):52-65, 1975.

The action of the microbial flora of the digestive tract on biliary acids metabolism was studied in germ-free and conventional, exposed male Fischer rats. The animals were fed semi-synthetic diet composed of 220 g of casein, 580 g of corn starch, 90 g of corn oil, 50 g of cellulose, 50 g of mineral mixture and a mixture of vitamins for 50 days. The animals also received 44,000 dpm of (4-^{14}C) cholesterol/g of the diet for 50 days. Due to the regular intake of labeled cholesterol, an isotopic balance was established, so that various chemical species of bile acids showed the same specific activity. This property was used to study bile acid distribution in the liver, intestines and feces. The bile acids were separated by thin-layer chromatography, and the radioactivity was determined by liquid scintillation counter. The masses of the bile acids were determined by 3-hydroxysteroid dehydrogenase test. The bile acids pool in the small and large intestines and cecum was twice as high in germ-free rats as in conventional rats, but fecal excretion was 20% lower in the former. The total bile acids amounted to 4.4 μM in the liver, 100.8 μM in the small intestine, 57.3 μM in the cecum, and 5.7 μM in the large intestine in germ-free rats, and they were 2.9 μM in the liver, 54.6 μM in the small intestine, 18.8 μM in the cecum and 9.1 μM in the large intestine of conventional rats. Cholic and muricholic acids constituted about 90% of the bile acids found in the small intestine of germ-free rats, while their feces also contained appreciable quantities of alpha-muricholic, chenodeoxycholic, and urodeoxycholic acids. Unidentified bile acids accounted for 20% of the fecal bile acids. This relatively large percentage of unknown bile acids in germ-free rats, compared to 40% unknown bile acids in conventional rat feces, made it impossible to determine the influence of bacterial metabolism on the two main pathways of bile metabolism in the rat.

6861 LIVER METABOLISM AND GLUCOGENESIS IN TRAUMA AND SEPSIS. *(E.)* Imamura, M.; Clowes, G. H. A., Jr.; Blackburn, G. L.; O'Donnell, T. F., Jr.; Trerice, M.; Bhimjee, Y.; Ryan, N. T. (Boston City Hosp., Boston, Mass. 02118). *Surgery* 77(6):868-880, 1975.

To determine whether amino acids are transported to the liver for conversion to glucose or for other purposes, and to study the glucogenic function of the liver, the uptake of glucogenic precursors and the production of glucose by the liver were studied. Healthy male and female pigs were used. Portal and hepatic arterial blood flows were measured and blood samples were obtained. The animals were starved for 4 days, then peritonitis was induced by ligation of the cecum below the ileocecal valve. After 3 more days, hemodynamic measurements and blood samples were repeated, and the surviving animals (15) were killed. The rate of glucogenesis was proportional to the sum of the glucogenic precursors taken up by the liver. Higher rates of glucose production were accompanied by elevated blood insulin values. Hepatic oxygen consumption and the rate of uptake of free fatty acids were also related directly to the glucogenic rate, the correlation coefficients being 0.69 and 0.74, resp. In the absence of shock, the liver function and hepatic energy production remained normal in post-traumatic and septic states. It is concluded that in sepsis the release of glucogenic substrates due to altered metabolism in peripheral tissues determines the rate of hepatic glucogenesis.

6862 ACTIVE CHRONIC HEPATITIS. ANIMAL MODEL: CHRONIC MURINE HEPATITIS INDUCED BY REOVIRUS TYPE 3. *(E.)* Stanley, N. F.; Joske, R. A. (Dept. Microbiology, Univ. Western Australia, Nedlands, 6009, Western Australia). *Am. J. Pathol.* 80(1):181-184, 1975.

Observations are reported of 20 yr experience with chronic murine hepatitis induced in more than 100,000 mice by reovirus type 3. Mice surviving a neonatal oronasal infection with the virus develop a progressive disease. Chronic hepatitis is a constant feature; affected mice are runted and jaundiced. These mice usually show a polymorphonuclear leukocytosis, with no evidence of bacterial infection and no antibody to endotoxin. Serum protein levels, especially in the γ-globulin fraction, are increased. Antibody response to sheep RBC, ovalbumin and reovirus type 3 are enhanced. There is an earlier onset and increased incidence of anti-smooth-muscle antibody compared to controls. The basic picture is of progressive liver disease accompanied by immunologic abnormality without the demonstration of virus. Affected mice show thymic atrophy, runting and an increased incidence of reticuloendothelial neoplasm. It is concluded that the value of the murine model lies in both the close clinical and laboratory similarities of the human and murine conditions, and also in the natural route of infection used and the rarity of development of the chronic condition.

6863 PREVENTION OF ALCOHOL-INDUCED FATTY LIVER BY NATURAL METABOLITES AND RIBOFLAVIN. *(E.)* Stanko, R. T.; Adibi, S. A. (Montefiore Hosp., Pittsburgh, Pa.). *Gastroenterology* 68(4):990, 1975.

6864 BILE ACIDS REGULATE INTESTINAL CELL TURNOVER. *(E.)* Raicht, R. F.; Deschner, E.; Salen, G. (VA Hosp., East Orange, N.J.). *Gastroenterology* 68(4):979, 1975.

SECRETION AND METABOLISM

Intestine

6927 A NON-DESTRUCTIVE METHOD FOR MEASURING INTESTINAL CELL TRANSIT TIME. *(Eng.)* Hagemann, R. F.; Cooper, J.; Poulakos, L. (Allegheny General Hosp., 320 E. North Ave., Pittsburgh, Pa. 15212). *Cell Tissue Kinet.* 8(4): 391-396, 1975.

A method is described for measuring intestinal cell transit time using the time of labeling of S phase crypt cells as the 'start' measurement and the time of lumenal digestion of these cells as the 'finish' measurement. Ha/ICR mice were injected with methimazole (1 mg, i.p.); 25 min later they were given sodium thiocyanate (0.05 mg) and 5 min later were given ^{125}I-iododeoxyuridine (^{125}I-UdR) (3 µCi). Methimazole was injected every 2 hr for 12 hr thereafter. Male Holtzman rats (5 mg methimazole, 4 µCi, ^{125}I-UdR), adult male gerbils (2 µCi ^{125}I-UdR), and adult beagle dogs (10 mg methimazole, i.v. every 3 hr, 10 µCi ^{125}I-UdR) were treated according to similar procedures. During methimazole administration, the animals' drinking water contained chlorothiazide (1 mg/ml), a diuretic. At various intervals beginning 24 hr after ^{125}I-UdR, the thyroid and jejunum were counted in a liquid scintillation spectrometer. In the rats, gerbils and mice, for which the intestinal cell transit times are known, the loss of intestinal radioactivity by cell loss from the villi was accompanied by a prompt rise in thyroidal activity. The transit times thus obtained corresponded to the previously established cell transit times in these animals (i.e., 42-46 hr in mice, 38-42 hr in rats, and 120-130 hr in gerbils). The net thyroid activity plots in the dogs, a species in which the transit time values are unknown, indicated an intestinal cell transit time of about 32 to 37 hr. Thus, the mammalian thyroid gland can be used as an *in situ* biological indicator for determining intestinal cell transit time without a requirement for tissue sampling.

6928 QUANTIFICATION OF PHYSIOLOGICAL CHANGES IN GUT ENDOCRINE CELLS: IMMUNOCYTOCHEMICAL AND RADIOIMMUNOASSAYS OF SECRETIN CELL FUNCTION. *(E.)* Polak, J. M. Pearse, A. G. E.; Bloom, S. R.; Joffe, S. N. (Hammersmith Hosp., London, England). *Acta Hepato-Gastroenterol. (Stuttg.)* 22(3):186-189, 1975.

Instrumentation and technology for random sampling of mucosal specimens were developed and are illustrated in five English White pigs by the response of the secretin cells to the instillation of acid into the duodenal mucosa. Acid (0.1 N HCl) was perfused at a constant rate through the duodenum and jejunum which were isolated and cannulated. Eight identical samples of mucosa were freeze dried and fixed in diethylpryrocarbonate vapor and subsequently embedded in paraffin wax. Sections of tissue were cut and subjected to indirect immunocytochemistry using peroxidase labeling; quantification was made using a Television Image conversion analyzer. In an illustration of a representative section of resting duodenal mucosa, six secretin cells are enclosed in circles which contain a heavy black brown deposit of the diaminobenzidine (DAB) polymer which is the final reaction product. In contrast, in a section of mucosa taken after 30 min perfusion with acid, there were five secretin cells which contained DAB polymer in much lesser amount. The mean fall in secretin levels calculated from the results of image analysis amount to 52% as compared to 72% from parallel radioimmunoassays. It is concluded that secretin is released in response to the presence of acid in the duodenum and that the results of immunocytochemical techniques can be quantified by image analysis to provide meaningful data for the interpretation of physiological changes in gut endocrine cells.

6929 THE PANETH CELL: A SOURCE OF INTESTINAL LYSOZYME.

(E.) Peeters, T.; Vantrappen, G. (Laboratorium voor gastrointestinale fysiopathologie, Katholieke Universiteit te Leuven, Belgium). *Gut* 16(7):553-558, 1975.

The presence of lysozyme as a Paneth cell secretory product was studied in the mouse. Small intestine was quickly removed from mice, frozen, and fixed in ethanol. Slices were covered with rabbit antilysozyme antiserum, washed and covered with fluorescent antirabbit immunoglobulin, and examined by fluorescence microscopy. For a separate perfusion study, NMRI mice had the jejunum incised 4 cm and 24 cm distal to the pyloric sphincter, and the 20 cm jejunal segment was perfused with saline at 4.0 ml/hr. The outlet was connected to a fraction collector. Each 1 ml fraction collected corresponded to 15 min of perfusion time. Pilocarpine was injected i.v. after a control period, and the perfusate was assayed turbidometrically for lysozyme. Amylase activity was also determined. Fluorescence microscopy showed a positive reaction in the Paneth cell region of the crypts. Faint fluorescence was seen in other mucous membrane cells. Fluorescence was absent when antilysozyme antiserum was replaced by normal rabbit serum, or when the antiserum was pre-incubated with the pure antigen. Injection of 4 mg of pilocarpine five min before dissection resulted in the disappearance of all crypt fluorescence, while a stream of fluorescence appeared between the villi. After 10 min, a granular fluorescent material was found on top of the villi. The perfusion studies showed initial high amylase levels which decreased over 2.5 hr to a low basal value. Lysozyme started out at a low basal value and remained stable. Pilocarpine injection caused a sharp rise in lysozyme level from the basal value (0.06-0.27 μg/ml) to 3.9 μg/ml, but amylase level was unaffected. Lysozyme concentrations were lower in starved animals (0.16 μg/ml) than in unstarved animals (0.31 μg/ml). It is concluded that lysozyme is present in and secreted by the Paneth cells, and can serve as a marker of Paneth cell function.

6930 OXIDATION-REDUCTION POTENTIALS IN THE CECAL CONTENTS OF RATS AND MICE.

(E.) Koopman, J. P.; Janssen, F. G. J.; van Druten, J. A. M. (Central Animal Lab., Catholic Univ., Nijmegen, Netherlands). *Proc. Soc. Exp. Biol. Med.* 149(4): 995-999, 1975.

The oxidation-reduction potential (ORP) in the cecal contents of conventional adult Wistar rats, Swiss ND_2 germ-free mice, and mice with a Colonization Resistance Factor flora (CRF-mice) was investigated. By using animals that were anesthetized (by α-chloralose) for a longer period of time, the authors attempted to eliminate the disturbing influence of oxygen. In addition, measurements were made under anaerobic conditions. For the rats, the ORP values reached a more or less constant level after about 30 min following the insertion of the electrodes in the cecum. The mean ORP at that time was -458 mV (SD = 45 mV). The mean ORP values for the mice showed a more gradual reduction than was found in the rats. The curves leveled off at about 100 min following the insertion of the electrodes. The mean ORP values 100 min after electrode insertion were: germ-free mice, +3mV (SD = 39 mV); CRF-mice, -554 mV (SD = 20 mV). In rats, the ORP value decreased after death; no decrease was observed in mice. No difference was found in the values obtained when measuring under aerobic or anaerobic conditions after death. The ORP values found in the present study are within the range of those found earlier in the artificial media used for the cultivation of strict anaerobes from the cecum of mice. The present study indicates that the ORP is at the same level *in vivo* and *in vitro*; consequently, it is likely that the cultivation of anaerobic bacteria *in vitro* as described in an earlier report is not negatively influenced by the ORP level.

6931 SUBSTRATE UTILIZATION AND OXYGEN CONSUMPTION BY CANINE JEJUNAL MUCOSA IN VITRO.

(E.) Lester, R. G.; Grim, E. (Dept. Physiology, Univ. Minnesota, Minneapolis 55455). *Am. J. Physiol.* 229(1):139-143, 1975.

Some aspects of canine jejunal mucosal metabolism of endogenous and exogenous substrates are described. Oxygen consumption, carbon dioxide production and substrate utilization in small pieces of jejunal mucosa removed from mongrel dogs were measured in standard Warburg respirometers. Experiments were performed with tissues from three dogs in which no exogenous substrate was added to the incubation flasks. The preparation typically continued to respire until the study was discontinued at 4 hr, the rate being relatively stable for 1 hr, after which there was slow decline to a final value which was about 2/3 the initial value. Regular cyclic fluctuations were present, with a period of 35 to 40 min and an amplitude of 30 to 40% of the mean value. Oxygen consumption was 0.21 μM/hr/mg, dry weight, and the respiratory quotient was 0.73. Addition of ^{14}C-labeled glucose or galactose (200 mg/100 ml) increased both oxygen consumption (0.33 and 0.28 μM/hr/mg, dry weight, resp.) and the respiratory quotient 0.90 and 0.83, resp.). Endogenous substrate metabolism was decreased by $[^{14}C]$ fructose (200 mg/100 ml), but not by glucose or galactose. Less than 15% of the metabolized glucose and fructose was degraded to CO_2. Of the metabolized glucose, 80% was recovered as lactate. Galactose disappeared at 1/7 the rate of glucose, but 40% of that metabolized was degraded to CO_2. It is suggested that the cycles observed in all experiments were due to an *in vivo* tissue mechanism.

6932 ENZYME PATTERNS AND PROTEIN ABSORPTION IN RAT COLON DURING DEVELOPMENT.

(E.) Helander, H. F. (Dept. Anatomy, Univ. Umea, Sweden). *Acta Anat.* 91(3):330-349, 1975.

The functional development of the rat colonic mucosa reflected in the contents of carbonic anhydrase, β-D-galactosidase, and acid and alkaline phosphatase was studied. Carbonic anhydrase activity reached a peak in 10-day-old rats which was about seven times the activity in the newborn rat. A peak value for β-D-galactosidase was detected 1 day after birth. Alkaline phosphatase displayed a pattern similar to that of β-D-galactosidase. The activity of acid phosphatase showed a flat curve with a poorly marked maximum at 5-10 days of age. A fairly weak staining reaction for carbonic anhydrase was found mainly at the surface of the mucosa during peak activity. A similar reaction held for β-D-galactosidase. Alkaline phosphatase activity was generally confined to the brush border, the lateral cell borders, close to the walls of vesicles in or subjacent to the terminal web region and in 0.5 to 2.0 μm large rounded bodies in the supranuclear cytoplasm. Most of the acid phosphatase activity was concentrated in the supranuclear bodies. Milk peroxidase and insulin enemas were absorbed in the infant rat colon, but this capacity was much reduced after weaning. It is suggested that the colonic mucosa may have a different function in the infant than in the adult.

6933 DIFFERENTIATION AND MATURATION OF CULTURED FETAL RAT JEJUNUM.

(E.) DeRitis, G.; Falchuk, Z. M.; Trier, J. S. (Harvard Medical Sch., Boston, Mass. 02115). *Dev. Biol.* 45(2):304-317, 1975.

To determine whether differentiation and maturation of mammalian intestinal mucosa require factors available only *in vivo* or factors available both *in vivo* and *in vitro*, jejunum from fetal (18th day of gestation) Sprague-Dawley rats was cultured in chemically defined medium using organ culture methodology. Jejunal segments were cultured in modified Leibowitz L-15 medium in room air at 37 C for 24, 48, or 72 hr, after which they were examined by light and electron microscopy. Uncultured jejunum had either no or very few rudimentary villi and was lined largely by undifferentiated stratified epithelium. Goblet cells were not seen. In contrast, villi were present in most of the 24-hr cultures, and simple columnar rather than stratified epithelium predominated. After 48 and 72 hr, villi were present in over 90% of the cultured segments and the stratified epithelium had disappeared. Goblet cells were seen in jejunal segments cultured 48 hr or longer in 47 of 74 fetuses. Electron microscopy further documented the progressive differentiation of the epithelium during culture. Microvilli increased in number and height, a terminal web developed in the apical cytoplasm, and the number of apical vesicles, mitochondria, and formed elements of endoplasmic reticulum increased in the absorptive cells. Jejunal lactase and alkaline phosphatase activity increased 9- and 7-fold, resp., during 72 hr of culture, while the activity of the mitochondrial enzyme ornithine carbamoyl transferase increased 4-fold. The data indicate that jejunum from 18-day fetal rats can be cultured *in vitro* for at least 72 hr in chemically defined medium and that, during culture, maturation of the jejunal mucosa takes place with the appearance of villi, conversion of stratified to columnar epithelium, and differentiation of individual epithelial cells.

6934 HUMAN INTESTINAL SUCRASE-ISOMALTASE. IDENTIFICATION OF FREE SUCRASE AND ISOMALTASE AND CLEAVAGE OF THE HYBRID INTO ACTIVE DISTINCT SUBUNITS.

(Eng.) Conklin, K. A.; Yamashiro, K. M.; Gray, G. M. (Stanford Univ. Sch. Medicine, Stanford, Calif. 94305). *J. Biol. Chem.* 250(15):5735-5741, 1975.

The interrelation of the hybrid sucrase-isomaltase complex and its active sucrase and isomaltase subunits in homogenates of human small intestine (obtained at autopsy 1-16 hr after death) was examined. The complex and its functional subunits were identified by Sephadex 6-200 (superfine) chromatography aided by isomaltase moiety affinity for dextran gel; this moiety bound strongly to the gel at 4 C, requiring two column volumes for elution. Bio-Gel P-300 chromatography, density gradient (100,000 to 300,000 x *g* at 4 C for 4-6 hr), and equilibrium centrifugation (300,000 x *g* for 72 hr and 97 hr at 4 C) demonstrated that the sucrase subunit and the isomaltase subunit are similar, but unequal in size (Stokes radius = 45, 43 Å; frictional ratio = 1.32, 1.30; $S_{20,w}$ = 6.9, 6.6; MW = 130,000, 120,000 resp.). The sucrase-isomaltase complex (Stokes ratio = 70 Å, frictional ratio = 1.61, $S_{20,w}$ = 9.8, MW = 280,000) appeared as an elongated hybrid molecule and was less symmetrical than the subunits. Apparent K_m and pH activity curves were indistinguishable for each enzyme in the hybrid of the free state. The complex accounted for 90% of the intestinal sucrase and isomaltase activities and was isolated and cleaved by 0.01 M β-mercaptoethanol/6 M urea treatment into subunits which have identical biochemical characteristics with the free sucrase and isomaltase moieties. Sodium dodecyl sulfate acrylamide gel electrophoresis also produced subunits with molecular weights very close to those for active free sucrase and isomaltase moieties, indicating that each α-glucosidase consisted of a single polypeptide chain. Immunization of rabbits with pure sucrase-isomaltase complex yielded a monospecific precipitating antibody which reacted with the hybrid and the sucrase moiety, but which showed minimal affinity for the isomaltase subunit; this provides further evidence that the sucrase-isomaltase molecule is a hybrid consisting of two distinct α-glucosidases. It is also suggested that the two nonidentical subunits act independently on their respective substrates.

6935 INTRACELLULAR DISTRIBUTION OF β-GALACTOSIDASES IN MUCOSAL CELLS FROM HOG SMALL INTESTINE.

(E.) Sato, M.; Yamashina, I. (Faculty Pharmaceutical Sci., Kyoto Univ., Japan). *Biochim. Biophys. Acta* 397(1):179-187, 1975.

The intracellular distribution of three β-galactosidases (hetero β-galactosidase, lactase, and acid β-galactosidase) in the hog small intestinal mucosa was studied. The mucosa was homogenized and separated into five subcellular fractions (I-V) by differential centrifugation. Purified brush borders and mucosal lysosomes were also prepared. The β-galactosidases were identified by hydroxylapatite column chromatography, and the various preparations were assayed for hetero β-galactosidase, lactase, sucrase, acid and alkaline phosphatases, glucose-6-phosphatase, NADPH-cytochrome c reductase, and cytochrome oxidase. Sucrase activities were higher in fractions III (lysosomal fraction) and IV (microsomal fraction) than in fraction I (nuclei and brush borders). Fraction III also contained significant amounts of microsomes, microvilli, and mitochondria, fraction II consisted mainly of mitochondria, and fraction IV contained microsomes, microvilli, and lysosomes. Lactase activity essentially paralleled the distribution of sucrose activity in the subcellular fractions, and most of the hetero β-galactosidase activity was found in fraction V (cytosol fraction). Some lactase and acid β-galactosidase activities were also found in the cytosol fractions. Sucrase activity was high in the purified brush borders, the lactase activity in this preparation being about 7-fold greater than in the homogenate and the hetero and acid β-galactosidase activities being lower than in the homogenate. The ratios of hetero β-galactosidase and acid β-galactosidase to lactase in the brush border preparations were 1:3.6 and 1:0.11, respectively. The lysosomal preparations contained low lactase and hetero β-galactosidase activities and high levels of acid β-galactosidase activity. It is concluded that acid β-galactosidase is a lysosomal enzyme and that lactase is localized in the brush borders.

6936 ADENYLATE AND GUANYLATE CYCLASE ACTIVITIES AND CELLULAR DIFFERENTIATION IN RAT SMALL INTESTINE.

(E.) Quill, H.; Weiser, M. M. (Harvard Medical Sch., Boston, Mass.). *Gastroenterology* 69(2):470-478, 1975.

Nucleotide cyclase levels and cyclic nucleotide phosphodiesterase activities were measured in the small intestinal villus and crypt cells of nonfasted female Holtzmann rats to determine possible correlations with cellular differentiation and subcellular localization. The intestinal epithelial cells were isolated into villus and crypt gradients by the method of Weiser. The different preparations were homogenized and the supernatant fractions were assayed for adenylate cyclase, guanylate cyclase, phosphodiesterase, and sucrase. The guanylate cyclase activity in the crypt cells was significantly lower than in the villus cells, the reverse being true for adenylate cyclase. There was no gradient activity for cyclic guanosine 3':5'-monophosphate phosphodiesterase, although cyclic AMP phosphodiesterase activity was lower in the villus cells than in the crypt cells. No villus to crypt gradient of cyclic AMP activity was detected in intestinal mucosa frozen rapidly in liquid nitrogen. When isolated villus cells were homogenized and fractionated by differential centrifugation, the highest specific activity of both adenylate and guanylate cyclase was in the 20,000 *g* pellet. A small amount of adenylate cyclase, but no guanylate cyclase, activity was found in the soluble fraction. The (Na^+, K^+)-ATPase-rich lateral-basal membrane fraction isolated from the 20,000 *g* pellet by sucrose gradient centrifugation showed a 5-fold greater specific activity for adenylate cyclase than was found in the homogenate; the guanylate cyclase activity of the membrane fraction was lower than in the homogenate. The specific activity of guanylate cyclase increased 5-fold with purification of the microvillus membranes (isolated from homogenates of mucosal scrapings), but this preparation had no detectable adenylate cyclase activity. Preparations of isolated nuclei contained no detectable adenylate cyclase activity and the nuclear guanylate cyclase activity was decreased in comparison with the homogenate. The data suggest that guanylate cyclase has a specialized role in the differentiated villus cell and that the cyclases may be interrelated, possibly reflecting the epithelial cell polarity for absorption and secretion.

6937 THE NUTRITIVE EFFECT OF GLUCOSE ON THE STRUCTURE AND FUNCTION OF JEJUNAL SELF-EMPTYING BLIND LOOPS IN THE RAT.

(E.) Menge, H.; Werner, H.; Lorenz-Meyer, H.; Riecken, E. O. (Medizinsche Universitats-Klinik, Marburg-an-der-Lahn, West Germany). *Gut* 16(6):462-467, 1975.

The effects of glucose, galactose and Ringer's solution on the development of mucosal structure and function were studied in jejunal self-emptying blind loops. Female Wistar rats were provided with a blind loop from the proximal jejunum. Beginning 5 days after operation, the animals were infused with 3 ml of the infusate three times/day for 27 days. Group I received an isotonic glucose (36.5 g/l) and NaCl (3.0 g/l) solution (nine rats) or Ringer's solution (control; nine). Group II received an isotonic galactose (36.5 g/l) and NaCl (3.0 g/l) solution (nine) and Ringer's (controls; nine). The blind loops were excised for histological examination and morphometric evaluation on day 32. Only rats infused with galactose lost weight during the first 4 days after operation. There was no difference in weight between any of the groups after this. There was a significant increase in villus height with infusion of glucose; the villus height to crypt length ratio was also increased. Maltase activity showed a marked rise with glucose infusion (47.3 U/g protein compared with control, 38.5 U/g protein). A reduction in peptidase activity was also observed with glucose. Infusion of galactose tended to lower dipeptidase levels. Glucose absorption was enhanced in loops perfused with both glucose and galactose, although the effect of galactose (2.07 mg/cm of intestine/hr) was not as great as that of glucose (2.23 mg/cm of intestine/hr). These results indicate an apparent increase in the number of transport sites for monosaccharides, which is induced by the presence of a substrate (glucose or galactose) within the experimental loop.

6938 THE INFLUENCE OF FOOD INTAKE ON THE DEVELOPMENT OF STRUCTURAL AND FUNCTIONAL ADAPTATION FOLLOWING ILEAL RESECTION IN THE RAT.

(E.) Menge, H.; Grafe, M.; Lorenz-Meyer, H.; Riecken, E. O. (Medizinische Universitats-Klinik, Marburg-an-der-Lahn, West Germany). *Gut* 16(6):468-472, 1975.

The influence of food consumption on adaptive changes in the intestinal mucosa was studied following ileal resection, under pair-fed and free-fed conditions. Female Wistar rats (14) underwent ileal resection and end-to-end anastomosis; another nine rats were sham-operated. For 3 days after surgery, the rats were fed with a sugar salt solution. Following this, nine of the ileal-resected rats were pair-fed and the remaining five were allowed food *ad libitum*. The pair-fed, ileal-resected rats had significantly lower body weights than either the sham-operated controls or the free-fed ileal-resected rats. There was no difference in the mucosal structure of controls and pair-fed ileal-resected rats. The free-fed group, however, had hypertrophic mucosae, with taller and wider villi, deeper crypts, larger epithelial cells and thicker muscular layers. Both glucose absorption and the glycyl-L-leucine activity were significantly increased in pair-fed and free-fed, ileal-resected rats. These data confirm the absence of changes at the cellular level, indicating that the stimulation of absorptive capacity results from an increase in the number of absorbing cells, rather than from an augmentation in the activity of individual cells.

6939 PROTEIN AND GLYCEROLIPID BIOSYNTHESIS IN ISOLATED EPITHELIAL CELLS OF NORMAL AND BILE-FISTULA RATS. *(E.)* O'Doherty, P. J. A.; Yousef, I. M.; Kakis, G.; Kuksis, A. (Dept. Biochemistry, Univ. Toronto, Canada M5G 1L6). *Arch. Biochem. Biophys.* 169(1):252-261, 1975.

Alterations in biochemical transformations accompanying the deprivation of lysophosphatidylcholine or choline in isolated intestinal epithelial cells were studied. Fat-filled cells were prepared from normal and 1-day bile-fistula rats. Protein synthesis from [1-^{14}C]leucine (2 µCi) was decreased 40 to 45% in cells from bile-fistula rats, and glycoprotein synthesis from [1-^{14}C]glucosamine (1 µCi), 25 to 30%. The synthesis of phosphatidylcholine from a variety of precursors was decreased 40 to 45% while no change was seen in the formation of either phosphatidylethanolamine or triacylglycerols. Chylomicron release was inhibited 70-80% in bile-fistula cells. *In vitro* addition of either lysophosphatidylcholine or choline (6-10 µM or higher, resp.) to bile-fistula cells resulted in greatly increased phosphatidylcholine and protein biosynthesis and an effective release of chylomicrons. It is suggested that biliary diversion may effectively starve the intestinal cells of choline, resulting in decreased phosphatidylcholine biosynthesis, which in turn causes decreased protein synthesis and incorporation into chylomicrons.

6940 EFFECT OF PUROMYCIN IN VITRO ON PROTEIN AND GLYCEROLIPID BIOSYNTHESIS IN ISOLATED EPITHELIAL CELLS OF RAT INTESTINE. *(E.)* O'Doherty, P. J. A.; Kuksis, A. (Dept. Biochemistry, Univ. Toronto, Ontario, Canada M5G 1L6). *Int. J. Biochem.* 6(6):435-441, 1975.

The early events accompanying puromycin poisoning of isolated intestinal absorptive cells *in vitro* were studied. Fat-filled mucosal absorptive cells were prepared from male Wistar rats. Analysis of the incorporation of [^{14}C]leucine (20 mCi/mM) into the total protein of intestinal epithelial cells showed a linear increase in uptake over the first 30 min for controls, after which uptake levelled off. The addition of long puromycin led to an 85 to 90% inhibition of protein synthesis at 1 hr. Addition of puromycin caused little inhibition of [^{14}C]glucosamine (30 mCi/mM) uptake in hr 1, and only a 10 to 20% decrease by hr 2. Addition of puromycin caused a 30 to 40% inhibition of chylomicron secretion. Triacylglycerol synthesis from [2-^{3}H]glycerol (200 mCi/mM) was not affected. Phosphatidylcholine showed a 35% inhibition by the end of hr 2. Addition of puromycin produced no change in the triacylglycerols of the cells or chylomicrons, while the specific activity of the phosphatidylcholines decreased. Addition of puromycin had no effect on the incorporation of 2-hexadecyl-[2-^{3}H]-glycerol (3.5 x 10^3 µCi/µM) into 1,3-diacyl-2-alkyl-*sn*-glycerols. Incorporation of 1-acyl-*sn*-[2-^{3}H]glycerol-3 phosphorylcholine (130,000 dpm/µM) into phosphatidylcholine was only inhibited 20 to 25%. It is concluded that the effect of puromycin is due to its interference with the normal biogenesis of the endoplasmic reticulum, which involves both protein and phospholipid biosynthesis.

6941 THE POSSIBLE ROLE OF PANCREATIC PROTEASES IN THE TURNOVER OF INTESTINAL BRUSH BORDER PROTEINS. *(E.)* Alpers, D. H.; Tedesco, F. J. (Washington Univ. Sch. Medicine, St. Louis, Mo. 63110). *Biochim. Biophys. Acta* 401(1):28-40, 1975.

The possible effect of pancreatic proteases on the turnover of intestinal brush border enzymes was examined in nine male Wistar rats subjected to 95% pancreatectomy. At time of sacrifice three to six months later, four animals were considered to have recovered pancreatic function; all four had a vitamin B12 absorption greater than 50% which did not increase with the addition of trypsin. In addition, the proteolytic activity of their intestinal juice was comparable to that of nonoperated control rats. The remaining five animals were judged to have pancreatic insufficiency and especially protease deficiency. Enzyme studies on homogenates of the proximal third of the small intestine revealed a 50% increase in specific lactase, sucrase, and maltase activities in all nine animals. Protein turnover was measured *in vivo* using double labeling with [^{3}H]- and [^{14}C] valine. Proteins with apparent molecular weights of about 200,000-270,000 turned over more rapidly than small proteins. The ^{3}H/^{14}C ratio ranged from 4.7 to 6.2 in animals without pancreatic insufficiency and from 2.3-3.1 in those with decreased pancreatic proteolysis. Estimates of relative synthetic rates of large brush border proteins were lower than normal in pancreatectomized animals, but were constant over the period of the labeling experiment. *In vitro*, using purified brush borders, unfractionated pancreatic enzymes removed sucrase, maltase and lactase, but not alkaline phosphatase and trehalase. A model is thus proposed for the normal catabolism of some large intestinal brush border proteins. It is suggested that the surface of intestinal absorptive cells is being constantly remodeled, and that certain surface enzymes are in part removed from the membrane by the action of pancreatic proteases.

6942 THE EFFECT OF DUODENAL JUICE ON THE INTRINSIC FACTOR (IF) ACTIVITY IN GASTRIC JUICE. *(E.)* Vatn, M. H. (Ulleval Hosp., Oslo 1, Norway). *Scand. J. Gastroenterol.* 10(1):49-53, 1975.

The effect of duodenal juice on intrinsic factor (IF) activity in gastric juice during basal conditions and during stimulation with gastrointestinal hormones was studied to evaluate the effect of refluxed duodenal juice on IF measurements. Gastric and duodenal juice was collected from six healthy subjects for 15 min basally and in seven 15-min periods of stimulation. The pH after reneutralization was between 6.8 and 7.6 in all samples. IF concentration was reduced by all of five samples of duodenal juice ($P < 0.05$). IF or unspecific viatmin B_{12}-binding concentrations were not significantly altered by pentagastrin (1 μg/kg/hr) stimulation. IF concentration was decreased by adding fourth to seventh period samples of secretin-stimulated (2 U/kg/hr) duodenal juice and incubating for 2 hr at 37 C. This small decrease was seen in all of six samples ($P < 0.05$) at all pH values. Unspecific B_{12}-binding concentration was increased in all samples with reduced IF concentration ($P < 0.05$). IF concentration was greatly reduced ($P < 0.05$) in all of six samples by first to third period samples of duodenal juice stimulated by 20% cholecystokinin (2 U/kg/hr), especially at low pH values. Unspecific B_{12}-binding showed similar values. Of 34 samples of gastric juice mixed with duodenal juice, 17 showed decreased intrinsic factor and unspecific B_{12}-binding concentrations. A simultaneous decrease of IF and increase of B_{12}-binding were seen in all samples with bilirubin concentrations above 1.5 mg/100 ml. These data indicate that IF measurements may be influenced by duodenal juice.

6943 EFFECT OF THYROIDECTOMY ON THE ACTIVITY OF α[SIC]-GLUCOSIDASES AND ACID HYDROLASES IN THE SMALL INTESTINE OF RATS DURING WEANING. *(Eng.)* Koldovsky, O.; Jumawan, J.; Palmieri, M. (Children's Hosp., Philadelphia, Pa. 19104). *J. Endocrinol.* 66(1):31-36, 1975.

The effect of thyroidectomy on the activity of the small intestinal β-glucosidases and acid hydrolases was studied in suckling Charles River rats. The pups were adrenalectomized on day 14 postpartum and half of them were thyroidectomized. At various times after surgery, the small intestine was divided into three segments and assayed for acid β-galactosidase, *N*-acetyl-β-glucosaminidase, β-glucuronidase, sucrase, maltase and protein. No sex differences were observed. Adrenalectomy slowed the growth of the animals and the small intestines; it also delayed the normal increase in the activities of sucrase and maltase and the normal decrease in the activities of acid β-galactosidase, β-glucuronidase, and *N*-acetyl-β-glucosaminidase during the third postnatal week. Simultaneous thyroidectomy had no effect on the adrenalectomy-induced inhibition of body weight and small intestinal growth, but it caused a further substantial delay in the maturation of the enzyme profile of the small intestine. The changes were observed in both the ileal and jejunal segments. The data indicate that the thyroid as well as the adrenals is involved in the regulation of enzyme activities during weaning, and that the thyroid can act independently of the adrenals on several intestinal enzymes.

6944 CYTOCHROME P-450 AND DRUG METABOLISM IN INTESTINAL VILLOUS AND CRYPT CELLS OF RATS: EFFECT OF DIETARY IRON. *(E.)* Hoensch, H.; Woo, C. H.; Schmid, R. (San Francisco Medical Center, Calif. 94143). *Biochem. Biophys. Res. Commun.* 65(1):399-406, 1975.

Drug-metabolizing activity in different cell populations of rat intestinal mucosa were investigated. Mature villous tip cells, functionally less differentiated intermediate villous cells and proliferating crypt cells were obtained from rats on various dietary regimens and assayed for benzpyrene hydroxylase and *p*-nitroanisole O-demethylase activity, and for cytochrome P-450 and b_5 content. Monooxygenase activity in microsomes from whole intestinal mucosa was highest in the upper small intestine and decreased progressively towards the terminal ileum. Mature villous tip cells contained more cytochrome P-450 and b_5 than those of more distal parts of the small intestine. The respective values for duodenal and ileal mucosa were: cytochrome P-450, 0.110 and 0.051 nM/mg of microsomal protein; and cytochrome b_5, 0.109 and 0.076 nM/mg. The activities of microsomal hemoproteins and drug metabolism in villous tip cells of duodenal mucosa were studied after maintenance on the following diets: standard chow diet; semisynthetic iron-supplemented diet; semisynthetic low iron diet for 2 days; and semisynthetic low iron diet for 2 days, followed by iron-supplemented diet for 24 hr. Cytochrome P-450 content and drug-metabolizing activity of villous tip cells after the third diet decreased to 42 and 13% of control values, but were restored within 24 hr in the last diet. These data suggest that intestinal drug metabolism is primarily localized in upper villous cells of duodenal mucosa, that cytochrome P-450 is synthesized in maturing epithelial cells as they migrate to the top of the mucosal villus, and that this process is critically dependent on dietary iron.

6945 EXPERIMENTAL PRODUCTION OF ELEVATED SERUM FOLATE IN DOGS WITH INTESTINAL BLIND LOOPS. II. NATURE OF BACTERIALLY PRODUCED FOLATE COENZYMES IN BLIND LOOP FLUID. *(E.)* Bernstein, L. H.; Gutstein, S.; Efron, G.; Wager, G. (Albert Einstein Coll. Medicine, Bronx, N.Y. 10461). *Am. J. Clin. Nutr.* 28(8):925-929, 1975.

The nature of the bacterially produced folate coenzymes present in intestinal blind loop fluid and the nature of the glutamate chain of these coenzymes were studied in canine jejunal and ileal blind loops. Twelve weeks after creation of each loop, the feculent material was removed and centrifuged. The supernatant fluid was removed, treated with mercaptoethanol, and eluted on standard DEAE Sephadex A-25 columns. The fluid was assayed with *Lactobacillus casei*, *Streptococcus faecalis*, and *Pediococcus cerevisiae*. Column chromatography of high and low blind loop fluid revealed four discernible peaks when assayed by *L. casei:* augmentation of loop fluid with authentic folate coenzymes indicated that peak I was 5-formyltetrahydrofolic acid; peak II, 5-methyltetrahydrofolic acid; and peak III, tetrahydrofolic acid; peak IV was not identifiable. Assays with *S. faecalis* revealed disappearance of peaks II and IV, suggesting that peak IV was not free folic acid. Assays with *P. cerevisiae* revealed disappearance of peak II only. Peak IV was therefore a reduced folate utilizable by *P. cerevisae* and *L. casei* but not by *S. faecalis*. When fractions of peak IV were exposed to guinea pig intestinal lysosomal conjugate and reassayed with *S. faecalis*, folates of peak IV became available to this organism. Thus, peak IV was indeed a reduced triglutamate, presumably 5-formyltetrahydrofolate triglutamate. The occurrence of this compound in blind loop fluid indicates that polyglutamates can survive undigested within the lumen.

6946 INTESTINAL VILLUS AND CRYPT CELL RESPONSE TO CHOLERA TOXIN.

(E.) Weiser, M. M.; Quill, H. (Harvard Medical Sch., Boston, Mass.). *Gastroenterology* 69(2):479-482, 1975.

The effect of cholera toxin on the adenylate cyclase activity of the small intestinal villus and crypt cells of fasted Holtzman rats (200 g each) was measured *in vivo* and *in vitro*. The rat abdomen was opened and two sections of midintestine (approximately 20 cm long and separated by 10 cm) were tied off and filled--the control loop with 0.154 M of NaCl and the test loop with cholera toxin (1 μg/ml in 0.154 M NaCl). Proximal and distal segments were used alternately for cholera toxin treatment. Villus tip to crypt cells were obtained in sequential order and pooled to give an upper, mid and lower villus fraction and a crypt fraction. Basal and fluoride-stimulated adenylate cyclase activities were measured after 3-hr incubation. Loops from proximal and distal segments showed similar responses to toxin treatment. Upper villus cell fractions exposed to cholera toxin showed a 3-fold increase in basal adenylate cyclase activity over controls. The lower villus cells also showed a significant increase in basal activity whereas crypt cell response was not significantly elevated. Fluoride-stimulated adenylate cyclase activity usually showed a slight decrease after exposure to cholera toxin. Low crypt cell adenylate cyclase activity was attributed to the lowered ability of cholera toxin to bind *in vivo* to crypt cells; the toxin did not appear to reach crypt cells in significant concentrations *in vivo* and incubation with ^{125}I-cholera toxin demonstrated binding only to villus cells. No response could be demonstrated for isolated villus or crypt cells incubated with cholera toxin *in vitro*. Thus, cholera toxin was found to exert its major effect in intestinal villus cells rather than the crypt cells, suggesting that the crypt cell does not participate in the major changes observed with cholera toxicity.

6947 EFFECTS OF CRUDE AND PURE CHOLERA TOXIN ON PROSTAGLANDIN RELEASE FROM THE RABBIT ILEUM.

(E.) Bedwant, J. R.; Okpako, D. T. (Dept. Pharmacology, Univ. Cambridge, England). *Prostaglandins* 10(1):117-128, 1975.

The effects of crude and pure cholera toxins on the release of prostaglandin-like substances (PLS) from the rabbit ileum were investigated *in vivo* and *in vitro*. The ileum of the rabbits was perfused with buffer alone (Krebs-bicarbonate or Krebs-phosphate) followed by buffer containing crude toxin (lyophilized crude culture filtrate of *Vibrio cholerae*) (50 mg/ml) or pure toxin (10 μg/ml), followed by buffer alone. In three *in vivo* experiments, the inclusion of crude toxin in the perfusion fluid was followed by a release of PLS from the ileum. The amount of PLS rose from non-detectable (< 5 ng - < 19 ng PGE_2 Eq/30 min) during perfusion with buffer alone to peak values of approximately 37.5 ng PGE_2 Eq/30 min during or after perfusion with toxin containing buffer. In contrast, no detectable PLS was released when ileal loops were perfused with pure toxin. In two *in vitro* experiments with crude toxin at concentrations of 5 and 50 mg/ml in each, PLS in amounts up to 107 ng PGE_2 Eq/g tissue were found after one to four hr of incubation in the higher concentration of toxin. The pure toxin did not cause any detectable release of PLS from the ileum. In rabbits treated with 16 mg/kg indomethacin, fluid accumulation was diminished in sacs injected with either crude or pure toxin. Treatment with 1.6 mg/kg had no effect. It is concluded that crude and pure toxin have quantitatively similar effects on the secretion of fluid into ileal sacs *in vivo*. The results support the view that prostaglandins do not play an essential role in the action of cholera toxin on ileal fluid secretion. Because crude and pure cholera toxin differ in their effects on prostaglandin release, there is need for caution when interpreting results obtained with crude preparations of bacterial toxins.

6948 INHIBITION OF GUANYLATE CYCLASE AND CYCLIC GMP PHOSPHODIESTERASE BY CHOLERA TOXIN.

(Eng.) Kiefer, H. C.; Atlas, R.; Moldan, D.; Kantor, H. S. (Northwestern Univ. Medical and Dental Sch., Chicago, Ill. 60011). *Biochem. Biophys. Res. Commun.* 66(3):1017-1023, 1975.

The effects of cholera toxin (injected *in vivo* into closed loops of distal ileum) on the activities of adenylate and guanylate cyclase and cyclic GMP phosphodiesterase were studied *in vitro* in rabbit small intestinal epithelial cells at periods 4 to 6 hr subsequent to toxin exposure. There was a simultaneous dose-dependent activation of adenylate cyclase and a deactivation of guanylate cyclase. In addition, the activity of phosphodiesterase catalyzing the hydrolysis of cyclic GMP was reduced in a dose-dependent fashion in most intestinal loops; approximately one of every 15 loops assayed failed to show a depression in cyclic GMP phosphodiesterase activity upon cholera toxin exposure, however. The values of the apparent dissociation constants representing the interaction of the toxin molecule (M.W., 84,000 daltons) with the receptors mediating all three observed cellular activities were similar: adenylate cyclase activation, $K_d = 5.0 \times 10^{-9}$ M; guanylate cyclase inhibition, $K_d = 4.4 \times 10^{-9}$ M; cyclic GMP phosphodiesterase repression, $K_d = 2.1 \times 10^{-9}$ M. The data indicate that cholera toxin interacts with a class of binding sites of average affinity represented by $K_d = 3.8 \times 10^{-9}$ M; this binding appears to be of profound importance to the intracellular balance between cyclic nucleotides which may play a vital role in the cellular regulatory machinery.

GENERAL

6969 MICROCIRCULATION OF THE CAT STOMACH. *(E.)* Svanes, K.; Skarstein, A.; Svanes, T. (Dept. General Surgery, Univ. Bergen, Norway). *Eur. Surg. Res.* 7(1):53-64, 1975.

Carbonized microspheres (15 µm in diameter) were used for estimation of the microcirculation in different layers and regions of the cat stomach. ^{169}Yb, ^{85}Sr and ^{141}Ce-labeled microspheres (2-3 million) suspended in 0.3 to 0.5 ml of 10% dextran were injected into the left cardiac ventricle of anesthetized male and female cats. Cats were divided into groups of controls (receiving microspheres labeled with ^{85}Sr), a group with gastrin labeling with ^{169}Yb, followed by i.v. infusion of pentagastrin (0.15-0.30 µg/kg/min), then injection of ^{85}Sr-labeled microspheres; a norepinephrine group, labeled with ^{141}Ce, followed by an i.v. infusion of the drug (2 µg/kg/min), and then by injection of ^{85}Sr-labeled microspheres. The last two groups were laparotomized and a gastric ulcer was induced by 20% acetic acid (0.3 ml, s.c.), resp. The majority of labeled microspheres in the mucosa samples were found in the propria and in the glandular layer, with only a few in the submucosa. Muscularis samples showed the majority of the labeled spheres in muscle tissue, with only 1 to 9% present in the submucosa. In cats with ulcers, blood flow was markedly increased in both mucosa and muscularis samples in the ulcer region, due to high flow in the inflammatory granulation tissue. It is concluded that this method gives an accurate picture of capillary blood flow in the glandular layer of the mucosa and in the muscularis.

6970 PEYER'S PATCHES, GUT IgA PLASMA CELLS AND THYMIC FUNCTION: STUDY IN NUDE MICE BEARING THYMIC GRAFTS. *(E.)* Guy-Grand, D.; Griscelli, C.; Vassalli, P. (Hopital Necker-Enfants Malades, Paris 75015, France). *J. Immunol.* 115(2):361-364, 1975.

Experiments on nude mice were designed to correlate the effects of thymus grafting on development of Peyer's patches, frequency of intestinal mucosa immunoglobulin A (IgA) plasma cells, and serum IgA levels. Three to five thymus fragments obtained from 16- to 20-day-old BALB/c fetuses were placed in the peritoneal cavity of 8- to 10-week-old nude mice with BALB/c background. Controls were normal BALB/c mice. Immunofluorescent staining and ^{3}H-thymidine labeling of cell suspensions or tissue sections were used to detect intestinal IgA plasma levels and T lymphocytes. Serum IgA levels were determined by Laurell crossed electrophoresis. Thymus grafts to nude mice caused a steady increase in the percentages of mouse T lymphocyte antigen^{+} lymphocytes: 8-35% in the spleen, 16-57% in the peripheral lymph nodes, 15-48% in the mesenteric lymph nodes, and 8-15% in the Peyer's patches at 30 and 100 days, resp. The Peyer's patches of grafted nude mice when compared to ungrafted nude mice increased in size and could not be distinguished from those of normal BALB/c mice. They possessed well-developed germinal centers, large numbers of rapidly dividing cells, increased T lymphocyte populations in the interfollicular and germinal centers, increased numbers of intestinal IgA plasma cells and intraepithelial T cells of the intestinal mucosa, and higher serum IgA levels. Thus, thymus grafting has a pronounced effect on the development of Peyer's patches germinal centers and on the contents of the intestinal mucosa in IgA plasma cells. These findings may explain the association of thymic defects, low serum IgA, and lack of intestinal IgA plasma cells observed in some immunodeficiency syndromes of man.

6971 THE EFFECT OF SYMPATHETIC NERVE STIMULATION ON ACID SECRETION, REGIONAL BLOOD FLOWS AND OXYGEN USAGE BY STOMACHS OF ANAESTHETIZED CATS. *(E.)* Grund, E. R.; Reed, J. D.; Sanders, D. J. (Medical Sch., Univ. Newcastle upon Tyne, England). *J. Physiol.* 248(3):639-647, 1975.

To determine whether splanchnic nerve stimulation has a direct inhibitory effect on parietal cell activity, oxygen consumption and extraction by the stomach were measured in cats during gastrin pentapeptide stimulation with and without concomitant splanchnic nerve stimulation. The fasted, anesthetized animals were subjected to pylorus ligation, after which a catheter was passed into the pyloric antrum. Both vagus nerves were sectioned and the splanchnic nerves were cut extraperitoneally on both sides; ring electrodes were placed on the distal ends of the splanchnic nerves. Gastric activity was stimulated by i.v. gastrin pentapeptide (20 µg/10 min) and the splanchnic nerves were continuously stimulated (10 Hz) for two consecutive 10-min periods. Gastric acid output was measured by electrometric titration to pH 7 and the oxygen concentrations in the arterial and gastric venous blood were measured using an oximeter. Splanchnic nerve stimulation significantly reduced the acid output and total gastric and mucosal blood flows produced in response to maximal gastrin pentapeptide infusion. The arterial hemoglobin concentration was also significantly reduced during splanchnic nerve stimulation, and the total gastric oxygen consumption was significantly reduced during the periods when the mucosal blood flow and acid secretion were inhibited. The data indicate that oxygen consumption and acid secretion decline in parallel during splanchnic nerve stimulation, but that the percent oxygen extraction by the stomach does not change significantly. These findings support the hypothesis that splanchnic nerve stimulation directly inhibits parietal cell activity.

6972 SUBCELLULAR LOCATION AND THE EFFECTS OF VARIOUS HORMONE STIMULI ON ADENYLATE CYCLASE IN THE INTESTINAL MUCOSA OF THE GUINEA PIG. *(Fr.)* Bouhours, D.; Bouhours, J. F.; Lambert, R. (Edouard Herriot Hosp., Lyon, France). *Biol. Gastroenterol. (Paris)* 7(4):275-283, 1974.

Female albino guinea pigs underwent food deprivation (18 hr) prior to cervical dislocation. Intestinal mucosa homogenate adenylate cyclase activity was assayed with and without NaF, in nonpurified brush border preparation (BB+N), in purified brush border preparation (BBp), and in 2,000 *g* pellet from brush border preparation supernatants, the resulting sediment having been called MP. Through testing, MP seemed to be made of impure lateral and basal membranes, BBp, of microvillus membranes noncontaminated by mitochondria and microsomes. The effect of adenylate cyclase was sought in the three preceding preparations; the MP fraction demonstrated the most activity followed by BB+N and then by BBp. But when NaF was added, even the BBp could become active. The activation mechanism of adenylate cyclase was presumed to be one of steric modification. This would explain the behavior of BBp; the enzyme would stay under the control of its regulatory protein until stimulation by NaF. The high activity of MP was tested for the presence of a hormonal factor or for a partial dislocation of the membranous structure. Three factors have been known to stimulate adenylate cyclase: (1) NaF, (2) choleria toxin, and (3) prostaglandins. Other hormones tested *in vitro* proved ineffective in stimulating intestinal adenylate cyclase. It appears impossible to link any intestinal hormone on a cause and effect basis to the secretion of adenylate cyclase.

6973 COLONIZATION OF THE GUT OF "GNOTOXENIC" RATS AND MICE BY TEN STRAINS OF STRICTLY ANAEROBIC BACTERIA: INFLUENCE OF THE HOST AND ITS DIET. *(Fr.)* Ducluzeau, R.; Raibaud, P.; Ladire, M.; Riottot, M.; Chopin, A. (Natl. Center Zootechnological Res., Jouy-en-Josas, France). *Ann. Inst. Pasteur (Paris)* 124B(4):517-532, 1973.

Ten strictly anaerobic bacterium species (*Pasteurella vulgata, Veillonella alcalescens, Clostridium difficile, Acuformis perennis, Streptococcus intermedius, S. putridus, Eubacterium parvum, Ristella putredinis, Inflabilis mangenoti,* and *Zymobacterium* sp.), isolated from the guts of conventional rats, were seeded in cecumectomized and noncecumectomized germ-free Fischer rats and C3H mice. The animals were kept on conventional diet, on commercial diet with additional lactose, on cow's milk, or on a semi-synthetic diet composed of 580 g of corn starch, 220 g of casein, 90 g of corn oil, 1 g of chromium oxide, 50 g of cellulose, vitamins, and inorganic salts. *Pasteurella, Acuformis,* and *Veillonella* were dominant in noncecumectomized rats and mice, regardless of diet, while *Eubacterium* and *Clostridium* were usually present in the subdominant flora. *Ristella, S. putridus* and *Zymobacterium* were also present in the subdominant flora of the rats, but they were absent in mice fed an identical diet. *Inflabilis* did not persist in any subjects. The addition of lactose did not modify this equilibrium in mice, but semi-synthetic diet caused a fall in the population of most species. In mice fed only cow's milk, the final equilibrium was between that observed with commercial diet and with semi-synthetic diet. Cecumectomy resulted in a drop in the bacterial population of the stomach and of the small intestine, and in the number of *S. putridus* throughout the digestive tract.

DIAGNOSTIC PROCEDURES

6985 AZYGOGRAPHY IN ESOPHAGEAL CANCER. *(Sp.)* Sans Segarra, M.; Curto Cardus, J.; Jori Sole, X.; Olazabal, A. (Principes de Espana Munic. Hosp., Barcelona, Spain). *Rev. Esp. Enferm. Apar. Dig.* 42(6):685-698, 1974.

Azygography is recommended for the selection of patients with operable esophageal tumors for surgery. After patients are fasted for 6-8 hr, a sedative is administered 1 hr before examination. With the patient in a prone position, a chest x-ray is taken. Then a local anesthetic (3-5 ml mepivacaine containing 1% epinephrine) is injected as far as the periosteum at the level of the 10th rib and posterior axillary line on the right side for the azygos major and on the left for the azygos minor. When the area is sufficiently anesthetized, a trochar is inserted so that contrast medium can be injected into the intercostal vein after more local anesthetic has been administered. It is recommended that the procedure be monitored on a television screen. Iodamide (15-20 ml) is injected as rapidly as possible, x-rays are taken during injection of the last ml of contrast medium, and changes in the azygogram are studied as the patient performs the Valsalva manuever. This demonstrates any delay in flow in the azygous system. Since some patients have normal findings on one side and a block at a distance from the tumor on the other, indicating the presence of lymph node metastases, bilateral examinations should by performed routinely. Marked reflux is considered indicative of hypertension in the azygous system which results from a block at some level in its path. In about 10% of the patients examined, thoracoaxillary collaterals were observed without any sign of hypertension. Few complications occurred. One patient developed pneumothorax and another was hypersensitive to the contrast medium; both complications resolved rapidly and spontaneously. In some patients, contrast medium diffused through soft tissues and the patients developed inflammatory tumefactions and pain which lasted 5-7 days. Local heat and antiinflammatory ointment produced reabsorption.

6986 THE BUDD-CHIARI SYNDROMES: RADIOLOGIC DIAGNOSIS. *(Fr.)* Bigot, J. M.; Chermet, J.; Monnier, J. P. (Hopital St. Antoine, Paris, France). *Ann. Radiol. (Paris)* 17(5):451-469, 1974.

The Budd-Chiari syndrome was defined as a secondary obstruction of the hepatic veins, the diagnosis of which was made by radiographic and phlebographic studies. Fifty patients (mean age 30 yr) were observed over the past 18 yr. The clinical aspects which brought the patients to the hospital were the following: possible decompensated hepatic cirrhosis with edema of the lower extremities or hepatomegaly. Absence of any etiology to this pseudo-cirrhotic syndrome as well as the observation of a collateral basithoracic, presternal and epigastric circulation were of high value. The existence of polycythemia and the use of laporophotography proved essential in the diagnosis. The methods used in this study were precise and sequential: inferior cavography, catheterization of the right heart, tentative selective retrograde catheterization of the hepatic veins and transhepatic transcutaneous venography (VTH), the latter being a precise technique with few risks. This was followed by selective arteriography of the celiac trunk and the superior mesenteric artery. The VTH seemed to be the only radiologic exam which would actually prove the syndrome. Three types of pictures were obtained through VTH: no opacification of the right hepatic vein, total ostial obstruction and dilatation with stasis in the hepatic veins. The overall arteriograph show increased density of the caudal lobe, hypervascularization of the right diaphragmatic dome, and hepatic hypervascularization. The results are confirmed by surgery.

6987 BARIUM OR GASTROGRAFIN: WHICH CONTRAST MEDIA FOR DIAGNOSIS OF ESOPHAGEAL TEARS? *(E.)* James, Jr., A. E.; Montali, R. J.; Chaffee, V.; Strecker, E. P.; Vessal, K. (Johns Hopkins Med. Inst., Baltimore, Md.). *Gastroenterology* 68(5): 1103-1113, 1975.

The effects of barium sulfate, alone and in combination with normal esophageal flora, on the mediastinum were compared with those of meglumine diatrizoate, a water-soluble contrast-medium. Twenty-nine domestic adult cats were divided into groups: operative controls, barium, meglumine diatrizoate, flora, meglumine diatrizoate plus flora, and barium plus flora. A total volume of 1 ml of substance was instilled into the mediastinum of each cat. The animals were sacrificed at serial time intervals following mediastinal injection. The water-soluble contrast media caused no significant histological reaction. Barium caused granuloma formation but had no additional deleterious effects when mixed with flora. Barium, due to its superior physical properties of mucosal coating and radiographic density, should be employed as the contrast agent of choice in difficult clinical problems with regard to esophageal tears. As a practical compromise, it is suggested that in patients with suspected tear of the esophagus, a limited upper gastrointestinal series with a water-soluble contrast agent be obtained. If this initial study is negative, it should then be repeated using barium as the contrast medium.

6988 EVALUATION OF CARBON-11 LABELLED PHENYLGLYCINE AND PHENYLALANINE FOR PANCREAS SCINTIGRAPHY. *(E.)* Vaalburg, W.; Beerling-van der Molen, H. D.; Woldring, M. G. (Academic Hosp., Univ. Groningen, The Netherlands). *Nucl. Med.* 14(1):60-66, 1975.

The tissue distribution of DL-α-phenylalanine-1-^{11}C and DL-α-phenyl-glycine-1-^{11}C in rats was studied, and the uptake of these compounds by the pancreas and liver was compared with the accumulation of L-selenomethionine-^{75}Se and ^{18}F-labeled amino acids. About 1 mg of the labeled amino acids were injected into the femoral veins of male Wistar rats under light anesthesia and the rats were killed at various intervals thereafter. The radioactivity in a blood sample taken before killing and in the liver, spleen, kidneys, and pancreas was determined. Based on the results, the ratios of the concentrations in the pancreas and liver were calculated and compared with the corresponding ratios reported in the literature for some ^{18}F-labeled aromatic amino acids and L-selenomethionine-^{75}Se. The results indicated that DL-α-phenylglycine-1-^{11}C, in spite of a small percentage of the administered dose reaching the pancreas, and DL-α-phenylalanine-1-^{11}C are better suited for pancreas scintigraphy than is L-selenomethionine-^{75}Sc.

6989 THE STATUS OF AND INDICATIONS FOR CELIOMESENTERIC ARTERIOGRAPHY IN GASTROINTESTINAL BLEEDING OF PANCREATIC ORIGIN.

(Fr.) Vankemmel, M. (Municipal Hosp., Lille, France). *Ann. Chir.* 27(6): 642-651, 1973.

The value and indications of celiomesenteric angiography in the diagnosis of gastrointestinal hemorrhages of pancreatic origin are presented on the basis of a patient material. Aneurysms of the splenic artery, intrahepatic arteries, localized dorsal pancreatic aneurysms, splenic and gastroduodenal arterial and arteriolar aneurysms, and pancreatico duodenal cirsoid aneurysms were diagnosed by celiomesenteric angiography in gastrointestinal bleedings of pancreatic origin. Preoperative arteriography permits logical surgical procedure adapted to the individual case, thus avoiding unnecessary gastric mutilation. In pancreatopathies, celiomesenteric arteriography furnishes information on the splenomesenterico-portal venous axis and on arterial lesions that may exist concurrently with venous involvement. Angiography provides a morphological picture indispensable for exploration for chronic pancreatitis, pseudocysts, or late evolutive complications of acute pancreatitis. Small opaque pseudo-aneurysms are pathognomonic of arterial erosion.

6990 MESENTERIC ANGIOGRAPHY IN INFLAMMATORY DISORDERS OF THE SMALL INTESTINE AND MESENTERIC INFARCTION.

(Ger.) Dombrowski, H.; Pemsel, H. K. (Univ. Med. Clin., Marburg, Germany). *Radiologe* 14(9):415-424, 1974.

The value of mesenteric angiography for diagnosis and differential diagnosis in inflammatory disorders of the small intestine, such as Crohn's disease, malabsorption syndrome, collagen diseases, and mesenteric infarction is discussed. Angiography in Crohn's disease is suitable for preoperative determination of activity in the small and/or large intestines, for the preoperative detection of adhesions and loop conglomerates, for differentiation between vascular process and lymphosarcoma in atypical forms of Crohn's disease, between Crohn's disease and ischemic colitis, and for the differential diagnosis of colitic stricture. Arterial hypervascularization, intense wall contrast, premature venous reflux, conspicuous distance between the inner contrasted wall layers and the subserous arteries, and transposition of higher intestinal arteries are the diagnostic features of different stages of Crohn's disease. Angiography can be used as an auxiliary diagnostic tool in certain special clinical cases of malabsorption syndromes. Angiography is valuable in the diagnosis of collagenoses, especially of periarteritis nodosa, which features irregularities in the vessel diameters, thrombotic occlusions, and miliary aneurysms of the medium and small arteries of the kidneys and of the gastrointestinal tract. In acute embolism of the superior mesenteric artery, angiography helps differentiate between acute proximal obturation and embolism in the peripheral branches. It is possible to localize the obturation, and to demonstrate a possible collateral perfusion. Reduced flow in the superior mesenteric artery, possible reflux into the aorta, and delayed or reduced filling of the peripheral section of the artery are found in thrombosis in the mesenteric vein.

6991 NEW TEST FOR PANCREATIC EXOCRINE FUNCTION: JEJUNAL PERFUSION OF AMINO ACIDS.

(Fr.) Ertan, A. (Departement de Gastroenterologie, Faculte de Medecine, Universite d'Ankara, Turquie). *Arch. Fr. Mal. App. Dig.* 64(2):107-114, 1975.

A jejunal perfusion of amino acids (JPAA) determined a release of cholecystokinin-pancreozymin (CCK), the effects of which were comparable to administration of a full dose of this hormone. Eight chronic pancreatitis patients, all alcoholics having an exocrine pancreatic secretion deficiency, and eight healthy controls were selected. Two probes (I and II, resp.) were placed at 40 cm below the duodenal junction (distal to the ligament of Treitz) and at the level of the fourth part of the duodenum. Probe I was subdivided into two smaller probes (A and B): probe A was used as a radio-opaque indicator; probe B was used to perfuse a mixture of amino acids. Probe II was subdivided into four smaller probes (C, D, E and F): C aspirated duodenal fluid, probe D insufflated air to facilitate probe C's work, probe E was used to perfuse a phenol solution (a nonabsorbed marker), and probe F aspirated gastric juices so that pancreatic juices would not be stimulated by acidification of the duodenum. Duodenal liquid was collected every 15 min on all 16 subjects and the pH, volume, bicarbonate concentration, trypsin, amylase, lipase, total protein, biliary acid and bilirubin levels were measured. The levels of the two latter were identical in both groups, suggesting that endogenous liberation of CCK stayed normal in chronic pancreatitis patients; all the other measured elements had lower levels for the CP group. This method may be of value in situations in which stimulation of the pancreas is desired.

6992 LIVER BIOPSY WITH GUIDANCE IN SCANNING. A PRELIMINARY REPORT.

(E.) Erasmie, U. (Karolinska Sjukhuset, S-104 01 Stockholm, Sweden). *Acta Radiol.* [*Diagn.*] *(Stockh.)* 16(1):49-53, 1975.

A method of introducing the biopsy instrument into the liver under fluoroscopic control for the use in liver scanning is presented. The method calls for scanning of the liver by a scintillation camera with a persistence oscilloscope. Following the i.v. administration of 2 mCi of ^{99m}Tc sulfur colloid, recordings are made in a.p., p.a. and lateral projections. Rings of metal of high radiation absorption serve as indicators. The ring is carefully adjusted to a position right above the lesion on the liver. Leaving the patient in an unchanged position, the head of the gamma camera is revolved and the location of the lesion is determined. In direct comparison with the known ring diameter, estimations of dimensions can be made on liver scan in levels paralled to the ring. Thus, the diameter of a lesion with a reduced isotope uptake may be determined and the size of the liver be approximated. Liver biopsy is performed with the patient in the same position as during the indication of the lesion. The biopsy instrument is inserted from a suitable position, usually the right side, horizontally at level with the center of the side ring. Under fluoroscopic control the instrument is introduced into the liver. The point of the needle should then be positioned centrally in the region of reduced isotope accumulation to permit sampling of tissue material. This technique was applied in 19 patients with the following results: the diameter of the lesion was between 3 and 6 cm in eight cases, 6 and 9 cm in eight cases, and more than 9 cm in three cases; cytology revealed carcinoma cells in ten patients; in five cases normal liver tissue was obtained. The results for the remaining four patients consisted of: a distended gallbladder with a stone in its neck; a case of biliary obstruction; a local, radiation-induced hepatitis; and a case in which diagnosis was uncertain. No complications in connection with the biopsies were encountered. It is concluded that liver scanning is a useful screening method of high accuracy.

6993 INDICATIONS FOR AND VALUE OF ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY. *(Ger.)*

Halter, F. (Inselspital, CH-3010 Bern, Switzerland). *Schweiz. Med. Wochenschr.* 105(15):476-480, 1975.

In a 2.5 yr period, retrograde cholangiopancreatographic (ERCP) examinations were performed on 159 patients. Premedication consisted of diazepam (5-20 mg i.v.) or mependine hydrochloride (1 mg/kg), either alone or combined with 5-10 mg diazepam. The papilla of Vater was seen in seven of the first 10 examinations, but duct systems were catheterized in only two cases (20%). With increasing experience it was possible to catheterize 85% of the last 130 patients. In 17 of the 32 cases in which catheterization could not be performed, it was impossible to see the papilla; the catheter slipped away in seven, three patients were uncooperative, and extravasation of the contrast medium occurred in two. In one case each, there was a Billroth II gastroenterostomy, a papillary carcinoma, and a nonfasting patient. The mean time required to perform RCP examinations was 54.4 min. In the 127 cases in which it was possible to introduce the catheter, both duct systems were visualized in 58 cases (43.3%), only the pancreatic duct in 44 (34.0%), and only the bile duct in 25 (19.6%). Diagnoses were established in 41 (73.1%) of 56 patients with clinical signs of biliary disease, in 15 (65.2%) of 23 patients suspected of having biliary and pancreatic disease, and in 48 (60.9%) of 80 patients suspected of pancreatic disease. In the 104 cases in which a diagnosis was established, findings were normal in 50 (31.4%) and pathological in 54 (34%). With the use of ERCP, the following findings were made: chronic pancreatitis in 20 cases, choledocholithiasis (16), pancreatic carcinoma (6), biliary carcinoma (2), papillary carcinoma (2), postoperative stenosis of the bile duct (1), papillary stenosis (2), cholecystolithiasis (2), insufficiency of the duodenal stump following a Billroth II procedure and cholecystectomy (1), and postcholecystectomy syndrome resulting from cutting of the right hepatic duct (1).

6994 COMPLICATIONS OF ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY: ANALYSIS OF 300 CONSECUTIVE CASES. *(E.)*

Zimmon, D. S.; Falkenstein, D. B.; Riccobono, C.; Aaron, B. (Manhattan Veterans Administration Hosp., New York, N.Y.). *Gastroenterology* 69(2):303-309, 1975.

Complications of endoscopic retrograde cholangiography were reviewed in 300 consecutive attempts at the procedure in 278 patients. In 79%, either the pancreatic and/or bile ducts were opacified. Retrograde pancreatograms were obtained in 192 cases and retrograde cholangiograms in 141 cases. In all there were 15 complications, a 5% incidence. In 62 cases, neither duct was opacified. Seven complications were drug-related, including behavioral disturbances in five, choking with emesis in one, and respiratory depression in one. Brief, self-limited pancreatitis after retrograde pancreatography occurred in five of 90 patients with pancreatic disease. Three patients developed septicemia within 72 hr after the procedure. In 85 cases, the procedure was performed in the absence of extrahepatic biliary disease; there were no complications. In 56 cases where the procedure showed extrahepatic pathology, three cases of sepsis occurred, a statistically significant increase in incidence. It is concluded that the procedure has no absolute contraindications, and compares favorably with other equally useful procedures.

6995 ACCURACY OF ULTRASOUND IN DIAGNOSING ABDOMINAL MASSES. *(Eng.)*

Richardson, R.; Norton, L. W.; Eule, J.; Eiseman, B. (Denver General Hosp., Denver, Colo. 80204). *Arch. Surg.* 110(8):933-939, 1975.

Over a 7-yr period, B-mode ultrasonography was performed in 246 patients with suspected abdominal masses. The accuracy of the ultrasonic diagnosis was evaluated in 105 (43%) of the cases, and proven correct in 60 (57%) of these 105. Of the remaining 141 patients, those who did not undergo surgery and whose diagnoses had been established by other means, the ultrasonic diagnosis agreed with the clinical diagnosis in 69 cases (31%). As confirmed by surgery, the accuracy of the ultrasonic diagnosis was highest for splenic masses (100%) and for aortic aneurysm (88%). In 56% of the patients, liver masses were correctly identified; gallbladder lesions were identified correctly in 38%. In diagnosing pancreatic disease, a 48% accuracy was obtained, but 64% of all pseudocysts were localized. In 56% of the renal masses, ultrasonography correlated positively. In 61% of the patients, abscess was accurately diagnosed. However, retroperitoneal adenopathy was correctly diagnosed in only 33%. It is concluded that abdominal ultrasonography, while accurate in diagnosing splenic and aortic masses, did not identify more than half of the other mass lesions. It is suggested that improvements in technique should upgrade the accuracy of this diagnostic tool.

6996 THE POSITION OF ECHOTOMOGRAPHY IN GASTROENTEROLOGY AND HEPATOLOGY: PRELIMINARY STUDY OF 135 CASES. *(Fr.)* Dofing, J. L. (No affiliation given). *Rev. Fr. Gastroenterol.* (103): 65-66, 68, 70-71, 1974.

Echotomography may be used in parellel with the clinical exam or to complement radiologic, scintigraphic or ultrasonic investigations. A total of 135 patients were studied and classified into three groups: those suffering from (1) palpable abdominal tumors (hepatomegaly without associated icterus or other palpable tumor); (2) jaundice with or without hepatomegaly or; (3) undetermined ailments without palpable mass or icterus. Forty-six hepatomegaly (without icterus) patients had confirmed diagnosis by this method. When used by a trained echotomographist, the technique could make or confirm a diagnosis without subjecting the patient to further, possibly more dangerous, tests (e.g., aortography for diagnosis of aneurysms in the abdominal aorta). Echotomography helped determine to which organ a palpable mass belonged. In 90% of the cases echotomography determined whether it was a liquid or a solid tumor and its exact location. Studying 17 patients with retention jaundice, correctness of diagnosis was as follows: 36%, exact disgnosis; 41%, indirect information; 33%, failure to diagnose (60% appropriate answers). Echotomography should fall into the routine exam for jaundice. In the last 18% of the studied population when echotomography was used after an ultrasonic or radiologic test, precise diagnoses were established. In conclusion, it seems the best use for this technique is in the exploration of abdominal tumors, palpable or not, and in searching for collected fluids.

GASTROINTESTINAL DISEASES

ESOPHAGUS

7069 MEASUREMENTS OF TRANSMUCOSAL POTENTIAL DIFFERENCE IN THE OESOPHAGUS, STOMACH AND DUODENUM UNDER ENDOSCOPIC CONTROL. *(E.)* Barbara, L.; Miglioli, M.; Di Febo, G.; Baldi, F.; Biasco, G.; Corinaldesi, R. (Dept. Internal Medicine, Gastroenterology, Univ. Bologna, Italy). *Rend. Gastroenterol.* 7(1):10-15, 1975.

Transmucosal potential differences were measured in organic lesions of the esophageal, gastric, and duodenal mucosa during endoscopy, and correlation of the results with the endoscopic and histologic appearance of the mucosa was attempted. Of 60 subjects, eight were apparently normal, seven had gastric ulcer, 14 had duodenal ulcer, four had gastric cancer, nine had chronic superficial gastritis, 15 had chronic atrophic gastritis, and one had dermatosclerosis. Exploratory electrodes were introduced *via* gastroduodenoscope and placed in direct contact with the mucosa, and reference electrodes were placed in contact with peripheral venous blood. At least 30 readings were taken per subject at various points (at least two readings per point). Three direct vision biopsy samples were taken from the stomach of each patient; basal and peak acid outputs were determined after pentagastrin stimulation. Controls showed mean potential differences for the esophagus, corpus and fundus, antrum and duodenum of -12.7, -45.48, -28.14, and -9.34 mV, resp. In the gastric ulcer patients, values were -10.56 mV at the level of the ulcer crater and -12.51 mV at the crater edge. Values of the corpus (-33.41 mV) and antrum (-19.0 mV) were significantly lower than control values. In the duodenal ulcer patients, values at the level of the crater were -4.58 mV and -5.3 mV at the crater edge. Values were also significantly lower than normal in the antrum and corpus. The dermatosclerosis patient had low values, except in the esophagus. Values were lowest at the angulus in which several non-bleeding erosions were present. The four gastric cancer patients had infiltrating and vegetating adenocarcinoma (ulcerated in one case) and infiltrating ulcerous carcinoma (two cases). Values were -13, -15, -5.5, and -6.5, resp. In the ulcerated zone, values went as low as -3 mV. Normal surrounding mucosa gave values ranging from -18.0 to -24.4. Histological examination showed grade 6 chronic atrophic gastritis in three cases, and grade 4 to 5 in the other case. No definite correlations of potential differences with endoscopic and histologic appearance were made.

7070 ESOPHAGEAL COLUMNAR EPITHELIAL β-GALACTOSIDASE AND β-GLUCURONIDASE. *(E.)* Berenson, M. M.; Herbst, J. J.; Freston, J. W. (Univ. Utah Coll. Medicine, 50 North Medical Drive, Salt Lake City, Utah 84132). *Gastroenterology* 68(6):1417-1420, 1975.

The activity of the lysosomal enzymes β-galactosidase and β-glucuronidase were compared in esophageal columnar, gastric fundic, and small intestinal epithelia. Esophageal biopsies were taken from four patients with midesophageal stricture and one patient with a deep esophageal ulcer. Gastric fundic and small intestinal tissue were obtained from patients undergoing endoscopy or peroral intestinal biopsy. All biopsy samples were homogenized. The mean β-galactosidase activity (as assayed using *p*-nitrophenyl-β-galactoside) in 10 gastric biopsies was 21.5 μmoles/g/hr; in eight small intestinal biopsies the mean was 28.9; in esophageal columnar epithelium the mean was 16.3. β-Galactosidase activity of gastric tissue was significantly less than the small intestine. Similarly, esophageal columnar epithelium was significantly less than small intestinal tissue, but did not differ from gastric tissue. The mean β-glucuronidase activity (as assayed with *p*-chloromercuribenzoate) in 10 gastric biopsies was 23.3 μmoles/g/hr; in seven small intestinal specimens the mean was 44.6; and in esophageal columnar epithelium the mean was 50.8. β-Glucuronidase activity in gastric tissue was significantly less than both small intestinal and esophageal columnar epthelium. Small intestinal and esophageal columnar epithelium did not differ significantly. It is concluded that esophageal columnar epithelium has enzyme characteristics which are dissimilar to both gastric fundic and intestinal tissue. This tends to corroborate previous findings of a structural and functional dissociation and suggests a metaplastic derivation.

7071 CAUSTIC STRICTURES OF THE OESOPHAGUS. *(E.)* Skene-Smith, H. (Dept. Radiology, Univ. Malaya, Kuala Lumpur, Malaysia). *Br. J. Radiol.* 48(572):646-648, 1975.

The radiological features of caustic strictures of the esophagus were studied in 16 females and six males aged 15-62 yr. The ages at caustic ingestion ranged from 1-45 yr, the ingestion being suicidal in nine cases. The structures were classified according to location (upper, middle, or lower third of the esophagus) and type (annular, short segment [less than 1/2 in. in length], and long segment). The lower third of the esophagus was involved in all the long segment strictures (16), but with sparing of the extreme distal portion in most cases. Irregularity of the stricture walls with an appearance similar to that reported in cases of intramural diverticulosis was a common finding (12 patients), but smooth strictures were also observed. Annular strictures (five) were noted with equal frequency in all portions of the esophagus, while short segment strictures (three) were noted only in the upper two-thirds. Of five long segment strictures involving the entire length of the esophagus, all had irregular walls. Dysphagia, chronic inflammation, and raised intraluminal pressure were present in patients with caustic strictures.

7072 THE ADVERSE EFFECT OF CHOCOLATE ON LOWER ESOPHAGEAL SPHINCTER PRESSURE. *(E.)* Wright, L. E.; Castell, D. O. (U.S. Naval Hosp., Philadelphia, Pa.). *Am. J. Dig. Dis.* 20(8):703-707, 1975.

The effect of chocolate on decreasing the lower esophageal sphincter (LES) pressure was studied in nine normal adult males using intraluminal end hole catheters. The responses to chocolate alone and to chocolate combined with agents known to increase LES pressure were evaluated. After basal LES pressure determinations, 120 ml of chocolate syrup mixed with 120 ml of distilled water was given p.o. to the subjects, who had fasted overnight. LES pressures were monitored for 1 hr. Mean pressure dropped from a basal level of 14.6 to a low of 7.1 mm Hg. On a subsequent day the subjects were given the same chocolate dose after basal recordings, and 15 min later were given 15 ml of a commercial antacid containing $Mg(OH)_2$-$Al(OH)_3$. Pressures were recorded for 1 hr after chocolate administration. Mean pressure dropped from a base of 13.3 to a low of 7.3 mm Hg at 15 min. On a third day the same dose of chocolate was given simultaneously with 25 mg of p.o. bethanechol. Four subjects were given 5 mg of bethanechol s.c. instead. With p.o. bethanechol, mean LES pressure dropped from a basal level of 18.4 to a low of 8.7 mm Hg at 15 min. With s.c. bethanechol, no decreases in pressure were observed; however, increases from a basal level of 16.5 to a peak of 25.3 mm Hg were seen at 30 min. Significant decreases in LES pressures after chocolate ingestion was demonstrated, confirming previous results by these authors. The results imply that neither antacid nor p.o. bethanechol administration reverses the action of chocolate in lowering LES pressure. However, s.c. bethanechol did reverse the LES pressure-lowering effect of chocolate.

7073 EFFECT OF PROSTAGLANDIN E_2 ON ESOPHAGEAL MOTILITY IN MAN.

(E.) Mukhopadhyay, A.; Rattan, S.; Goyal, R. K. (Baylor Coll. Medicine, Houston, Tex. 77025). *J. Appl. Physiol.* 39(3):479-481, 1975.

The effects of prostaglandin E_2 (PGE_2) on upper and lower esophageal sphincter pressures and on esophageal motility were studied in 12 normal adults, using intra-esophageal catheters. The luminal pressures were measured with three water filled side hole catheters glued together; the holes were 2.5 cm apart. The middle hole was placed at the sphincter, and pressures were recorded at 1 min intervals. A solution of 750 μg of PGE_2 in 150 ml of 5% dextrose was given by continuous i.v. infusion in varying, randomized doses over 5 min (doses were 30 min apart). The effect on lower esophageal sphincter (LES) pressure was measured in five subjects. The mean percent pressure fall at 5 min was 8.5, 21.3, 33.0, 61.6 and 52.0 for doses of 0.05, 0.1, 0.2, 0.4 and 0.8 μg/kg/min, resp. The effect on upper esophageal sphincter (UES) pressure was measured in three subjects, using doses of 0.4 and 0.8 μg/kg/min; no significant fall in pressure was observed. Peristalsis was studied with the catheter openings 10 cm apart so as to position them in the upper, middle and lower parts of the esophagus; peristalsis was initiated by dry swallows. Five subjects were studied using continuous infusion of PGE_2. Resting pressures were unaffected. The amplitude of contractions in the upper portion was unchanged, but was "significantly reduced" in the lower and middle esophagus. The speed of peristalsis was 4.9 cm/sec *versus* 3.6 cm/sec in the upper half and 5.4 *versus* 6.2 cm/sec in the lower half during dextrose infusion and PGE_2 infusion, resp. It is suggested that PGE_2 may selectively influence smooth muscle motor function in the esophagus. PGE_2 caused a dose-dependent reduction in LES pressure but did not affect UES pressure. The authors also suggest that PGE_2 reduces the amplitude of peristaltic contractions in the lower part of the esophagus.

7074 PRESSURE, TENSION, AND FORCE OF CLOSURE OF THE HUMAN LOWER ESOPHAGEAL SPHINCTER AND ESOPHAGUS.

(E.) Biancani, P.; Zabinski, M. P.; Behar, J. (Yale Univ. Sch. Medicine, New Haven, Conn. 06510). *J. Clin. Invest.* 56(2):476-483, 1975.

The influence of probe diameter on lower esophageal sphincter (LES) pressure and force of closure was studied, and the tension developed by the human LES and esophageal circular muscle was examined *in vivo*. Pressure and diameter characteristics were determined in 14 normal controls and in 19 patients with reflux esophagitis by the separate and random introduction of single motility catheters, attached to a plexiglas "olive" (0.25-1.0 cm in diameter). LES pressure in normal subjects was higher with the 0.25 cm olive, lower with the 0.5 cm olive, and gradually increased with the 0.75 and 1.0 cm olives. LES pressure in esophagitis patients remained low at all olive diameters. LES pressures were significantly different when measured pressures of competent and incompetent sphincters were compared at various probe diameters. Competent sphincters showed pressure differences only with probes between 0.50 and 0.75 cm. LES pressure increased at all probe diameters after successful fundoplication. Administration of the auticholinergic Pro-Banthine caused the pressure-diameter curves for competent sphincters to approximate those of patients. Urecholine stimulated pressures of incompetent sphincters and the pressure-diameter curves became similar in magnitude and shape to those of competent sphincters. Peak esophageal pressures in response to swallowing increased with larger probe diameters. The length-tension relation of the circular muscle increased continuously as the diameter increased for both competent and incompetent sphincters. Force and tension curves were similar in both types of sphincter. It is concluded that competent and incompetent sphincters have distinctly different pressure-diameter characteristics.

7075 CORRELATION OF LOWER ESOPHAGEAL SPHINCTER PRESSURE AND SERUM GASTRIN LEVEL IN MAN.

(E.) Wright, L. F.; Slaughter, R. L.; Gibson, R. G.; Hirschowitz, B. I. (Veterans Administration Hosp., Birmingham, Ala. 35233). *Dig. Dis.* 20(7):603-606, 1975.

The relation between lower esophageal sphincter (LES) pressure and simultaneous serum gastrin level was studied in 35 consecutive patients. Of these, seven served as controls; nine had gastroesophageal reflux and hiatus hernia (Group I), and the remaining 19 had no symptoms of reflux (Group II). Group II included eight patients with dysphagia, seven with chest pain, three with abdominal pain and one with persistent vomiting. Hiatus hernia was present in five Group II patients (IIA) and was not present in 14 Group II patients (IIB). The LES pressure of Group I was significantly lower (9.7 cm H_2O) than that of groups IIA (36.8) and IIB (25.6). The serum gastrin levels were not significantly different (129, 74 and 116 pg/ml, resp.). There was no correlation between individual LES pressure and individual serum gastrin level. In patients with abnormalities either of serum gastrin levels or the LES, there was no relation between these two factors. It is concluded that gastrin has no major physiologic role in the maintenance of sphincter tone.

7076 COMPARATIVE EFFECTS OF METOCLOPRAMIDE AND BETHANECOL ON LOWER ESOPHAGEAL SPHINCTER PRESSURE IN REFLUX PATIENTS.

(E.) McCallum, R. W.; Kline, M. M.; Curry, N.; Sturdevant, R. A. L. (Veteran's Admin. Wadsworth Hosp. Cent., Los Angeles, Calif.). *Gastroenterology* 68(5):1114-1118, 1975.

The effects of p.o. metoclopramide (10 and 20 mg), bethanecol (25 mg) and placebo on lower esophageal sphincter (LES) pressure and serum gastrin concentration were compared in 15 male patients with symptoms of gastroesophageal reflux. The LES pressure was measured by a rapid pull-through technique in patients after an overnight fast. The mean basal LES pressure on the four study days ranged from 5.4 to 5.6 mm Hg. Each drug produced a significant increase in pressure compared with the placebo. Metoclopramide at 20 mg produced a significantly higher pressure from 30-60 min after ingestion than either the 10 mg dosage of metoclopramide or bethanecol. LES pressures after 10 mg metoclopramide or bethanecol were not significantly different. The peak of LES pressures for the 15 subjects ranged from 4.3-15.0 mm Hg for placebo (mean, 9.2); 3.0-19.3 mm Hg for 10 mg metoclopramide (mean, 11.9); 8.4-23.5 mm Hg for 20 mg metoclopramide (mean, 15.8); and 4.5-19.5 mm Hg for bethanecol (mean, 11.7). The peak change in LES pressure from basal and the peak LES pressure were each significantly correlated with the basal LES pressure after 20 mg metoclopramide. Only the peak LES pressure was significantly correlated with basal pressure after 10 mg metoclopramide. There was no correlation between these two parameters and the basal LES pressure after bethanecol. Mean serum gastrin concentrations were not altered by any drug. Bethanecol produced statistically significant but small decreases in diastolic blood pressure and in pulse rate after 40 min. These data confirm previous findings of a correlation between basal LES pressure and rise in pressure after metoclopramide. It is suggested that metoclopramide be considered in a clinical trial in the treatment of gastroesophageal reflux.

7077 CONSERVATIVE SURGICAL TREATMENT OF REFLUX ESOPHAGITIS AND ESOPHAGEAL STRICTURE.

(E.) Herrington, Jr., J. L.; Wright, R. S.; Edwards, W. H.; Sawyers, J. L. (Vanderbilt Univ. Medical Cent., Nashville, Tenn.). *Ann. Surg.* 181(5):552-566, 1975.

Operative dilatation accompanied by an antireflux precedure was used in the treatment of 17 consecutive patients with advanced esophageal stricture and reflux esophagitis during a 3-yr period. The patients included nine men and eight women, aged 46-90 yr. Symptoms of reflux esophagus were present from 18 months to 30 yr. Preoperative procedures included barium examination of the esophagus and upper gastrointestinal tract, cinefluoroscopy, and esophagoscopy with biopsy. The stricture was of the longitudinal type in 10 patients and a short, distal, and annular stricture was found in the remaining seven cases. Simultaneous ante- and retrograde dilatation was carried out at operation in all cases. A Nissen fundoplication was performed in 15 patients, one had a Hill posterior gastropexy, and the remaining patient had a Belsey repair. Of the 17 patients, 16 survived surgery, and were studied postoperatively. Of these 16, one died soon after surgery of cardiovascular complications. Excellent clinical results were obtained in 11 cases, with no abdominal discomfort and no dietary restrictions. Mild and intermittent abdominal discomfort was experienced in four patients. During the postoperative follow-up, six patients required from one to three esophageal dilatations during the early postoperative period, and two patients with severe longitudinal strictures required monthly dilatations up to one yr. It is suggested that this simplified surgical approach directed toward correction of reflux and preservation of organ tissue should be attempted before more radical surgery.

7078 EFFECT OF FUNDOPLICATION ON THE LOWER ESOPHAGEAL SPHINCTER.

(E.) Bowes, K. L.; Sarna, S. K. (Dept. Surgery, Univ. Alberta, Edmonton, Alberta T6G 263, Canada). *Can. J. Surg.* 18(4):328-334, 1975.

Manometric measurements were made of the lower esophageal sphincter (LES) before and after fundoplication, to determine whether the alleviation of symptoms after this procedure can be attributed to either the creation of or improved function of a physiologic sphincter. A modified Nissen fundoplication was performed in 26 patients with heartburn and regurgitation; 20 of these had hiatus hernia. Manometry was performed before and 3 months after surgery; cadaver studies were also made. Complete recovery was noted in 24 patients. Symptoms reoccurred in one patient after 3 months, and in another, after 26 months. The common cavity test (simultaneous increases in gastric and esophageal size during abdominal compression) was positive in 22 patients before surgery, and in only the two with recurring symptoms postoperation. The acid perfusion test was positive in 25 patients before fundoplication (mean time, 267 sec). The time required for reproduction of these results was increased in all 26 after surgery, and in seven, results were negative (mean time, 616 sec; $P < 0.01$). Resting LES pressure increased from a mean of 12.6 presurgery to a mean of 16.5 cm H_2O postsurgery. An increase in LES pressure was seen in 15 patients, there was no change in four, and in seven, the pressure fell. It is suggested that increases in sphincter pressure after fundoplication are secondary to extrinsic narrowing, and do not indicate creation of a physiologic sphincter.

7079 MEDICAL AND SURGICAL MANAGEMENT OF REFLUX ESOPHAGITIS: A 38-MONTH REPORT ON A PROSPECTIVE CLINICAL TRIAL.

(E.) Behar, J.; Sheahan, D. G.; Biancani, P.; Spiro, H. M.; Storer, E. H. (Veterans Admin. Hosp., West Haven, Conn., 06516). *N. Engl. J. Med.* 293(6):263-268, 1975.

A controlled prospective and randomized study was performed to compare posterior gastropexy with anterior fundoplication, and to determine factors influencing selection of patients for medical or surgical treatment. The patients studied included 51 men with symptoms of chronic reflux and objective evidence of reflux esophagitis for 2 yr or more. Of these, 31 were randomized into groups of surgical (15) and medical patients (16); the remaining 20 were non-randomized patients receiving medical treatment. Surgical treatment consisted of a Belsey Mark IV alone in ten men, and this combined with the Hill method in five. Medical treatment consisted of head elevation (15 cm), bland diet, weight reduction and liquid antacids. All patients were followed for 20 to 46 mo. After operation, 11 of 15 patients had no symptoms of reflux, with a negative acid infusion test, except for one patient on one occasion. The esophagus appeared normal at endoscopy. Only three patients in the randomized medical group and four in the non-randomized group became asymptomatic with a negative acid infusion test and normal esophagus at esophagoscopy. The correlation of symptomatic and objective responses to both surgical and medical management was good. Patients with excellent to good response to surgical treatment had an increase in resting sphincter pressures persisting for up to 3 yr ($P < 0.001$). The response to medical management correlated well with the severity of the esophagitis and the degree of sphincter incompetence. These results indicate that at least during the first 3 yr, surgical treatment is more effective than current medical management in patients with severe reflux symptoms.

7080 HISTOLOGIC ABNORMALITIES IN REFLUX ESOPHAGITIS.

(E.) Behar, J.; Sheahan, D. C. (VA Hosp., West Haven, Conn.). *Arch. Pathol.* 99(7): 387-391, 1975.

Esophageal mucosal response to gastroesophageal reflux was studied in patients with heartburn with normal endoscopic appearance of the esophageal mucosa. Histological findings were compared in 15 control patients without gastroesophageal symptoms and 40 consecutive male patients with heartburn (postprandial, substernal burning pain, or postural changes), with or without regurgitation or dysphagia, for at least two yr prior to admission. All subjects had upper gastrointestinal roentgenograms, esophagoscopy, acid perfusion tests, esophageal manometry, intraesophageal pH study, maximal histamine test, and multiple esophageal biopsies. Heartburn was the most prominent symptom in 20 patients with mild esophagitis, and four of these also had regurgitation. The radiologic appearance of the esophagus was normal in these patients. The mean lower esophageal sphincter pressure was significantly lower than that of the controls. Patients with severe esophagitis had heartburn (95%), regurgitation (65%), dysphagia (40%), and low-grade bleeding (25%): all showed either mucosal friability or acute or chronic ulcerated lesions. Histologic examinations showed lymphoid aggregates in 50% of controls, and in 85% and 65%, resp., of patients with severe and mild esophagitis. Neutrophils were observed in 5% and 40%, resp., but were absent in control samples. Patients with mild and severe esophagitis had papilla higher than 50% of the mucosal thickness in 95% and 100%, resp., and a basal zone more than 15% of mucosal thickness in 95% and 94%, resp. Both abnormalities were seen in patients with mild and severe esophagitis in at least two biopsy specimens in 95% and 94%, resp. Of the controls, 47% had elongated papillae and 13% had a hyperplastic basal zone; none had both abnormalities together. These results confirm the validity of the use of the simultaneous presence of elongated papilla in the lamina propria and basal cell hyperplasia of the squamous epithelium in at least two biopsy specimens as diagnostic criteria of reflux esophagitis.

7081 ACHALASIA AND ESOPHAGEAL CARCINOMA. STUDIES IN EARLY DIAGNOSIS FOR IMPROVED SURGICAL MANAGEMENT.

(E.) Carter, R.; Brewer, L. A., III. (Dept. Surgery, Univ. California, Irvine, Calif.) *Am. J. Surg.* 130(2):114-120, 1975.

Four patients with achalasia and carcinoma were studied, and 221 cases of this association were reviewed in the literature to determine salient features of early diagnosis. The average age at the appearance of esophageal carcinoma in achalasia patients was 48 yr, in contrast to 64 yr for esophageal cancer in general. The average duration of the achalasia was 17 yr. Men were affected three times as often as women; this is a reversal of the frequent prevalence of achalasia in women. The most common site of origin was the middle third of the esophagus. The earliest signs were unexplained gastrointestinal bleeding or anemia. Other presenting symptoms were: recurrence of dysphagia, blood-tinged regurgitation, retrosternal or back pain, excessive weight loss, development of clubbing, and unexplained general deterioration. The lesions were often bulky, polypoid and largely epidermoid; they were easily missed on esophagography and esophagoscopy due to retention of food, and were rarely resectable, resulting in poor prognosis. There were indications that stasis esophagitis is premalignant. Early myotomy to relieve obstruction may be preventative, but once megaesophagus has developed, obstruction is usually permanent. Thorough cleansing of the esophagus prior to esophagography and esophagoscopy is emphasized, and esophageal washings, endoscopic cytologic study and biopsy are recommended as highly accurate diagnostic procedures. It is concluded that diagnosis must be early if curative resection is to be possible.

7082 PROBABLE PATHOGENIC RELATION BETWEEN SYSTEMIC MASTOCYTOSIS AND REFLUX ESOPHAGITIS.

STOMACH

7134 GASTRIC POLYPECTOMY. *(E.)* Seifert, E.; Elster, K. (Medizinische Hochschule, Hannover, Germany). *Am. J. Gastroenterol.* 63(6):451-456, 1975.

The histological findings of direct biopsy were compared with those of total excision in 75 gastric polyps removed by electroresection through a fiberscope, and a new histological classification of gastric polyps was developed based on 244 gastric polyps in 161 patients. The polyps were recovered *in toto* by suction or special grasper forceps. In 53 of 75 cases, discrepancies of histologic diagnosis were observed. The most frequent cause of discrepancy was the mixed form of epithelial polyp. Superficial excision very often yielded a pattern of foveolar hyperplasia, suggesting the biopsy was taken from a hyperplastic polyp. The hyperplastic gastric polyp, occurring in 14.8% of the patients with a single polyp, corresponded to the hyperplastic colonic polyp in structure and pathogenesis. Its histological criterion was the presence of finger-like, elongated crests and correspondingly deep stretched pits, resulting in a somewhat papillary structure. The adenomatous gastric polyp, occurring in 47.7% of patients with solitary gastric polyps, revealed structural peculiarities which exclude a pathogenetic relation with the adenomatous colonic polyp. This polyp apparently has an intermediate position between hyperplasia and adenoma. The real adenomatous polyp, a true adenoma, was very rare and occurred in only 7.4% of the cases with solitary polyps. Six patients had generalized gastric polyposis. In 92 sites of resections, out of a total of 176 sites, healing was complete at the end of one wk. The following classification of gastric polyps is suggested: focal hyperplasia, hyperplasiogenic polyp, adenoma, proliferation of glandula neck with epithelial atypia, and early gastric cancer types I and IIA. The findings suggest that gastric polyps are generally not precancerous lesions though cancer does occur in rare cases. Neoplasia does not appear to be related to number of polyps, to site, but rather presumably to inherent biologic activity.

7135 FIBEROPTIC ENDOSCOPY IN TREATMENT OF CORROSI INJURY OF THE STOMACH. *(E.)* Chung, R. S. K.; DenBesten, L. (Veterans Administration Hosp., Iowa City, Iowa 52240). *Arch. Surg.* 110(6):725-728, 1975.

Three patients with corrosive injury of the esophagus and/or stomach were studied by multiple endoscopies to document the natural history of corrosive injury. A 47-yr-old alcoholic who drank 355 ml of 23% HCl developed intense abdominal pain and vomited dark red mucoid material. Physical examination revealed erythema of the palate and posterior pharynx with tenderness of the epigastrium. Endoscopy showed hemorrhagic erosion of the esophagus. The patient was treated with nasogastric suction, i.v. fluids and antibiotics and steroids. Endoscopy on the sixth day revealed a 3 cm length of mild esophageal erythema and gangrenous changes in the gastric antral mucosa. The patient was operated, and full-thickness necrosis was observed on the serosa, which extended to the transverse mesocolon. Gastric antrectomy with Billroth I reconstruction was followed by uneventful recovery. A 45-yr-old male who drank 59 ml of 30% NaOH vomited red blood and had melena 4 days after ingestion. Endoscopy on the fifth day revealed extensive hemorrhagic areas in the stomach, most marked in the antrum. He was treated similarly to the first patient. Two weeks post-injury, repeat endoscopy showed the antrum to be scarred and edematous. The patient was treated surgically and recovered. A 45-yr-old male ingested 10 g of mercury bichloride and 75 mg of valium. Presenting symptoms were as above. Two weeks post-injury, endoscopy revealed erosions of the gastric mucosa most severe in the antrum. Forty days post-injury, the mucosa had improved and granulations were noted. The patient made an uneventful recovery. The acute stage involves hemorrhagic erosions and ulcerations of the mucosa, which gradually heal and fibrosis with decreased vascularity results, while gangrenous mucosa suggests full-thickness necrosis.

7136 MEASUREMENT OF IMMUNOREACTIVE GASTRIN IN GASTRIC MUCOSA. *(E.)* Malmstrom, J.; Stadil, F. (Rigshospitalet, Copenhagen, Denmark). *Scand. J. Gastroenterol.* 10(4):433-439, 1975.

A method for measuring gastrin in gastric mucosa was developed, and the distribution of gastrin in the stomach of pig, dog, cat, rabbit, and man was examined. Biopsy specimens were frozen, boiled, and homogenized. The gastrin content was measured by radioimmunoassay. Monoiodinated 125-I-SHG (synthetic human gastrin) was used as tracer. Gastrin was found in measurable amounts in all specimens examined, but the content was considerably higher inside the antrum. The highest concentration was found in man. In corpus biopsies from 21 subjects, the gastrin content was 78 ng/g mucosa. The border between the corpus and the gastrin rich antrum was sharp, but apart from this no particular pattern of gastrin distribution was apparent in the two parts of the stomach. Duodenal ulcer patients, control patients, and normal subjects had high gastrin content in the stomach, whereas patients with gastric carcinoma and gastric ulcers had low. In 44 patients with duodenal ulcer, the antral gastric concentration was 21.3 μg Eq/g mucosa; in 15 patients with prepyloric ulcer, 23.0; in 10 patients with gastric ulcer, 5.9; and in 16 patients with gastric carcinoma, 7.9. The control group consisted of 10 healthy volunteers and 12 patients with minor abdominal complaints. Mean antral gastrin concentrations were 28.1 and 20.7, resp. Human mucosa contained 8-10 times more gastrin than in dogs and 4-8 times more than in pigs. The results agree with previous studies that antral gastrin content in duodenal ulcer patients and normal subjects does not differ and clearly indicates that gastrin content is not increased in duodenal ulcer.

7137 INTRAMURAL INJECTION OF ETHANOL UNDER DIRECT VISION FOR THE TREATMENT OF PROTUBERANT LESIONS OF THE STOMACH. *(E.)* Otani, T.; Tatsuka, T.; Kanamaru, K.; Okuda, S. (Center Adult Diseases, 3-3, Nakamichi 1-chome, Higashinari-ku, Osaka 537, Japan). *Gastroenterology* 69(1):123-129, 1975.

Local injection of ethanol was used to remove gastric polyps and wide-based polypoid growths in dogs. This method was also used in the treatment of early gastric cancer in poor-risk patients. Ulcers were produced in mongrel dogs by bleomycin, mitomycin, OK-432, acetic acid and ethanol by intramural injection of various concentrations. Ethanol in a concentration of 95% was the most effective, producing immediate changes in the gastric mucosa which delineated the size of the ulcer. The depth of ulceration could be controlled and the ulcer healed readily. Gastroscopic injection with 95% ethanol was used to treat 54 patients with pedunculated (21 patients), narrow-based sessile (eight) and wide-based sessile polypoid lesions (25). Of 54 cases, 35 were hyperplastic or adenomatous polyps, 17 showed atypical hyperplasia and two had early gastric cancer, type II a. Complete eradication was confirmed by biopsy in all patients with atypical hyperplasia and early gastric cancer. Of 54 cases, treatment was not successful in three: one with wide-based sessile growth and two with pedunculated polyps. Complete healing with scar formation was seen in 43 cases within 6 weeks. It is concluded that polyp removal by intramural injection of ethanol is appropriate for the management of early gastric cancer in low-risk patients.

7138 INTRAMURAL VASCULAR CHANGES IN STOMACHS REMOVED BECAUSE OF BLEEDING—AS VISUALIZED WITH INDIAN INK—. *(E.)* Nagao, F.; Ikeuchi, J.; Kjijma, M.; Narikawa, T. (Jikei Univ. Sch. Medicine, Japan). *Jikeikai Med. J.* 21(3-4):249-258, 1975.

Gastric intramural vascular changes in stomach during or shortly after bleeding were determined under a microscope in 41 surgical specimens after visualizing the vessels with indian ink. A relation between the patient's circulatory disturbance due to hemorrhage and the features of the gastric vascular damage was sought. The degree of circulatory disturbance due to gastric bleeding was graded as mild (Group I), moderate (Group II), or serious (Group III) according to the response of the patient to a test transfusion given rapidly in a volume up to 1000 ml. The main pathological features observed in the bleeding groups were such changes as rupture of the large or capillary blood vessels at an ulcer crater; rupture, dilatation or tortuosity of the mucosal capillary vessels; and rupture or tortuosity of the submucosal vessels. The presence of the pathological changes was most marked in Group III (6 patients), and rupture of the large blood vessels was only seen in this group. Two specimens in Group III had no arterial rupture but showed a high degree rupture of the mucosal and ulcer's capillary, which may explain their serious bleeding. The outstanding feature of Group II (14 patients) was a high incidence of marked rupture of the mucosal capillary, which should explain bleeding in this group. Mild bleeding of Group I (21 patients) may be explained by the fact that this group had no bleeding from an ulcer and that rupture of the mucosal capillary was not severe. It is concluded that the rate of gastric bleeding and the vascular status of bleeding lesions can be correlated to some extent.

7139 GASTROSCOPIC OBSERVATIONS RELATED TO BIOPTICAL HISTOLOGY IN HEALTHY MEDICAL STUDENTS.

(E.) Myren, J.; Serck-Hanssen, A. (Ulleval Hosp., Oslo 1, Norway). *Scand. J. Gastroenterol.* 10(4):353-355, 1975.

Gastric mucosal samples from ten healthy volunteers were studied by gastroscopy with histology in directed biopsy specimens. Gastroscopy was performed after an overnight fast and an i.v. injection of 1 ml of pethidin with 0.3 mg of atropine. Degrees of mucosal alterations were categorized as: no alteration (0), slight changes (1), moderate (2), and pronounced reddening and mucus covering (3). A normal mucosal folding was recorded as 2, decreased folding was recorded as 1, and increased folding was recorded as 3. Directed biopsies (three to eight) were taken from the antral mucosa, and from the mucosa of the greater and lesser curvatures. Normal mucosal folding was found in all subjects. None had mucosal reddening or mucus covering of more than slight grades. Gastroscopy showed normal mucosa in four, probably normal in two, and superficial gastritis in four. Histology revealed a normal mucosa in the antrum of six subjects, normal lesser curvature mucosa in seven and normal at the greater curvature in eight. There was a good correlation between gastroscopic observations and bioptical histology on directed biopsies in six subjects.

7140 IS INTESTINAL METAPLASIA OF THE GASTRIC MUCOSA A PRE-MALIGNANT LESION?

(E.) Reynolds, K. W.; Johnson, A. G.; Fox, B. (Charing Cross Hosp., London, England). *Clin. Oncol.* 1(2):101-109, 1975.

The histological and clinical evidence indicating that intestinal metaplasia of the gastric mucosa is premalignant is reviewed. Histologically, the normal surface columnar epithelium of the gastric mucosa is secretory in function whereas the intestinal surface is both absorptive and secretory. In intestinal metaplasia, there is a morphological and histochemical transformation to a small bowel type of epithelium. It appears that with intestinalization, the gastric mucosal surface epithelium exchanges a secretory for an absorptive function. Clinical evidence indicates that intestinal metaplasia frequently occurs in the same stomach with carcinoma, and that it often occurs closely adjacent to the carcinoma. Furthermore, there is some evidence that metaplasia precedes neoplastic transformation and that the incidence of subsequent carcinoma in patients with intestinal metaplasia is higher than the predicted incidence for the population as a whole. A fairly close connection between endoscopic appearances and histological evidence of intestinal metaplasia has recently been demonstrated; such studies have shown an association between intestinal metaplasia and x-ray negative dyspepsia, as well as between metaplasia and x-ray negative dyspepsia, as well as between metaplasia and gastric ulcer and carcinoma. Although the connection between intestinal metaplasia and carcinoma is not proven beyond doubt, there is sufficient evidence that the former is premalignant to outline a scheme of surgical management: patients showing intestinal metaplasia should be followed-up by regular endoscopy; benign gastric ulcers should in most cases be removed by Billroth I gastrectomy; and duodenal ulcer should be treated by procedures such as highly selective vagotomy rather than polya gastrectomy or gastro-jejunostomy, the former being less likely to produce a gastritis. Antrectomy-en-Roux may prove to be a beneficial prophylactic procedure in patients with severe dyspepsia, bilious vomiting, and well-established intestinal metaplasia.

7141 MICROSCOPICAL CANCER OF THE STOMACH — A STUDY ON HISTOGENESIS OF GASTRIC CARCINOMA.

(E.) Nagayo, T. (Aichi Cancer Center Res. Inst., Nagoya 464, Japan). *Int. J. Cancer* 16(1):52-60, 1975.

To elucidate the histogenesis of gastric cancer preceded by "chronic gastritis," 67 foci (58 cases) of cancer less than 5 mm in diameter were examined histologically. The resected stomachs in all 58 cases were photographed and histological specimens from the main lesion and other parts of the stomach were embedded in paraffin and stained with hematoxylin, eosin, and PAS. Most of the minute cancerous foci were found in the mucosa of the antrum or angulus and were most frequent in the lesser curvature. In all but two cases, these minute foci occurred with peptic ulcer (42 cases) or gastric cancer (14 cases) and were found unexpectedly during the course of routine histological examinations. Minimal erosion was observed in 31 foci, tiny mucosal depressions were seen in ten foci, and no recognizable macroscopic changes were seen in 26 foci. Eighteen foci were located near the main lesion, while 40 were located far from it; seven foci were found in the mucosa adjacent to an ulcer scar. The histological changes in the minute foci were closely correlated with the grade of intestinal metaplasia: well- or moderately well-differentiated adenocarcinomas always occurred in combination with a high degree of intestinal metaplasia; poorly differentiated adenocarcinomas were associated with slight or no metaplasia. Regardless of histological type, the microscopic cancerous changes were always observed in the transitional zone between the foveolar epithelium and pyloric glands. The foci composed of differentiated adenocarcinoma cells were always seen on the deepest layer of the metaplastic mucosa or in the place where the metaplastic foveolar epithelia were situated, and the poorly differentiated adenocarcinomas were primarily found in the middle layer of the nonmetaplastic gastric mucosa. It is concluded that chronic gastritis is the most important and essential change for the development of gastric cancer. Foci in the flat mucosa can be used as a prototype for studying the histogenesis of gastric cancer from this condition.

7142 GASTRIC CANCER SCREENING IN OSAKA. *(E.)*

Aikawa, K. (Center Adult Diseases, 1-3-3 Nakamichi, Higashinari-Ku, Osaka, Japan). *Prevent. Med.* 4(2):154-162, 1975.

An epidemiological, clinical and administrative study of gastric cancer, being carried out in cooperation with the Center for Adult Diseases in Osaka, Japan, is described. The mass-screening program for gastric cancer was originally conducted using mobile units equipped with photofluorographic apparatus in the community and several industrial and business enterprises in a mass-screening program at the Center was later introduced. Gastric cancer was detected in 0.33% of the 78,404 persons examined during the period June 1961-December 1970; approximately 1/3 of these persons had early-stage cancer. The program efficiency of the mobile-unit program was evaluated in a 3-yr study involving 50.5% of the persons aged 40 yr and over living in an agricultural district in the Osaka Prefecture. About 55% of all new cancer cases in this district were detected by mass screening, 77.8% of the gastric cancer cases between 40 and 60 yr of age being detected in this manner. The 5-yr survival rate was significantly higher among those who received mass examination than among those who did not. The program in this district has now been in operation for 10 yr, and the age-adjusted mortality rate from gastric cancer was slightly lower in the second 5-yr period than in the first 5-yr period. In addition, the initial beneficial effects of the mass examination program appeared to last for 2 to 3 yr. At the Center, examinees are screened by a televised X-ray system as well as by gastrocamera and cytologic examination in some cases. The results to date indicate that the Center is more efficient in detecting abnormalities than the mobile units, this being particularly true of early stage gastric cancer. The rates of all gastric diseases except gastric polyps were higher among males than females. It is recommended that a cooperative cancer prevention system be established to meet increasing demands for mass screening in order to decrease the number of cancer deaths.

7143 GASTRIC FUNCTION IN PRIMARY HYPERPARATHYROIDISM IN MAN. *(E.)*

McGeown, M. G.; Connell, A. M. (Belfast City Hosp., Belfast, Northern Ireland). *Irish J. Med. Sci.* 144(6):217-226, 1975.

Gastric function was studied preoperatively in 24 men and 31 women with primary hyperparathyroidism. Six patients had hyperparathyroid bone disease, 44 had renal stones without bone disease, and five had hypercalcemia. All patients were closely questioned for dyspeptic symptoms, evaluated following a barium meal, and given a Kay's augmented histamine test for gastric acid secretion. Tests for antibodies to gastric parietal cells and thyroid were carried out in 20 patients, and serum gastrin in the fasting state was estimated before and after parathyroidectomy in 10 additional patients whose barium meals and pentagastrin tests were normal. Symptoms of dyspepsia were present in 41% of the males and 31% of the females, and active or healed duodenal ulcers were found in 29% of the males and 16% of the females. Six patients had hiatus hernia and one a diverticulum of the duodenum. None of the patients had a gastric ulcer. Kay's augmented histamine test revealed achlorhydria in 11% of the patients and hyperchlorhydria in another 11%, the remaining patients showing normal acid secretion. The acid secretion did not differ significantly from that in a control group of euparathyroid patients without duodenal ulcers. In the hyperparathyroid patients, there was no relation between the basal or posthistamine secretion of acid and the maximum serum calcium concentration. Gastric parietal cell and thyroid antibodies were not detected in any of the patients tested, including five with achlorhydria. Fasting serum gastrin levels were normal in seven and slightly raised in three patients before parathyroidectomy; following surgery, the levels were increased in three of the nine patients tested and unchanged in the others. It is concluded that there is an increased incidence of dyspepsia and duodenal ulcers among patients, particularly male patients, with primary hyperparathyroidism.

7144 IS CHRONIC GASTRITIS A REVERSIBLE PROCESS? FOLLOW-UP STUDY OF GASTRITIS BY STEP-WISE BIOPSY. *(Eng.)*

Rosch, W.; Demling, L.; Elster, K. (Dept. Internal Medicine, Univ. Erlangen-Nurnberg, Erlangen, Germany). *Acta Hepatogastroenterol. (Stuttg).* 22(4):252-255, 1975.

Step-wise biopsies along the minor and greater curves of the gastric mucosa of 36 patients (13 female, 23 male, mean age 49 yr) were performed in 1971 and in 1974 to 1975 in order to gain a representative idea of gastritic changes in the stomach. A comparison of the histological changes revealed identical findings in 15, progression of superficial gastritis in nine, and regression of superficial gastritis in seven. Regression of chronic atrophic gastritis was observed in five patients. In one patient an essentially normal mucosa was found in all biopsy specimens, and in two other patients, parietal cells reappeared without any specific therapy.

7145 STIMULI FOR HEPTADECAPEPTIDE GASTRIN RELEASE: A COMPARISON OF ORAL AND INTRAVENOUS ARGININE-MONOCHLORIDE AND OXO IN NORMAL, VAGOTOMIZED AND ANTRECTOMIZED PATIENTS. *(E.)*

Vinik, A. I.; Kalk, W. J.; Dent, D. M.; Barbezat, G.; Grant, B. J.; Bank, S. (Groote Schuur Hosp., Capetown, South Africa). *Gut* 15(11):97-100, 1975.

The effects of i.v. arginine (10 mg/kg/min for 30 min), p.o. arginine (30 g) and p.o. Oxo (4 cubes) on serum gastrin responses in man were compared in nine normal, six vagotomized, and three antrectomized patients. Basal gastrin concentrations were similar in the control groups for p.o. and i.v. arginine and the Oxo meal, ranging from 26-77 pg/ml. This contrasts with the lower 26.4 ± 3.4 pg/ml in the truncal vagotomized patients and the undetectable levels in antrectomized subjects. I.v. arginine caused a sharp early rise in serum gastrin concentration from a basal of 48.3 ± 2.14 pg/ml to almost three times the basal concentration at 15 min in control subjects. With p.o. arginine there was no rise in serum gastrin concentration. P.o. Oxo feeding caused only a twofold increase in gastrin above the basal concentration. I.v. arginine had no effect in antrectomized and vagotomized subjects. The reason for the absence of gastrin response to p.o. arginine is not apparent, but taken in conjunction with the marked response elicited by the i.v. route, this suggests that arginine is ineffective as a gastrin stimulant by local application to the antrum in man; it may require absorption, with high blood concentration, to act on the gastrin releasing mechanism.

7146 INHIBITORY EFFECT OF L-GLUTAMINE ON GASTRIC IRRITATION AND BACK DIFFUSION OF GASTRIC ACID IN RESPONSE TO ASPIRIN IN THE RAT.

(E.) Okabe, S.; Honda, K.; Takeuchi, K.; Takagi, K. (Faculty Pharmaceutical Sciences, Univ. Tokyo 7-3-1 Hongo, Bunkyo, Tokyo, Japan). *Dig. Dis.* 20(7):626-631, 1975.

The effect of L-glutamine on aspirin-induced gastric lesions at different time intervals was examined. Prevention of back acid diffusion by L-glutamine was also studied in intact and vagotomized rats. Gastric lesions were induced in pylorus-ligated male Donryu rats with 100 mg/kg of aspirin. Aspirin induced gastric lesions at 1 hr after intubation, and lesion formation reached a maximum after 3 hr. L-Glutamine (750 mg/kg) produced a 90% reduction in aspirin-induced gastric lesions. There was a slight but significant increase in gastric secretion by combined aspirin and L-glutamine (319.4 mOsM/kg) at 1 and 3 hr. There was a marked inhibition of H^+ loss by L-glutamine and a corresponding increas in Na^+. Diffusion of H^+ in vagotomized rats into the gastric mucosa and release of Na^+ was not altered by aspirin. L-Glutamine alone or in combination with aspirin inhibited back diffusion of H^+ in vagotomized rats. It is suggested that the inhibition of L-glutamine of aspirin-induced gastric lesions is due to an initial, direct protective effect on the gastric mucosa, and to a subsequent prevention of back acid diffusion.

7147 STATISTICAL EVALUATION OF PREVENTIVE USE OF GLUTATHIONE AGAINST SIDE-EFFECTS OF SURGICAL ADJUVANT CHEMOTHERAPY IN GASTRIC CANCER PATIENTS.

(E.) Itoh, I.; Nakazato, H.; Taguchi, T.; Onoda, T. (Natl. Cancer Cent. Hosp., Tokyo, Japan). *Jpn. J. Clin. Oncol.* 5(1):19-28, 1975.

The ability of glutathione (GSH) to prevent the side-effects manifested during surgical adjuvant mitomycin C chemotherapy was evaluated in 374 cases of gastrectomy for stomach cancer. Of the 374 cases, 174 (controls) were given mitomycin C on and after the day of surgery (total 0.8 mg/kg, i.v.) and twice weekly thereafter (0.08 mg/kg/day, i.v.). The remaining 173 patients were treated similarly, but in addition were given GSH (600 mg/kg/day) i.v. daily for 2 weeks from the day of surgery followed by 600 mg/day p.o. until the last day of mitomycin C administration. The control and GSH groups were similar in terms of 33 background factors, including sex, age, preoperative general condition, and surgical findings. Mitomycin C administration was suspended prior to completion of the total prescribed dose for reasons other than the side-effects in a comparable number of patients from both groups. Discontinuation of mitomycin C treatment due to side-effects was significantly reduced in the GSH group (10.4%) in comparison with the control group (20.3%). In addition, the incidence of abnormally low WBC values (<3000) after the start of mitomycin C treatment was significantly reduced in the GSH group compared with the control group. The two groups did not differ in terms of the incidence of decreased thrombocyte and RBC counts after mitomycin C treatment. The incidence of abnormal SGOT values and the manifestation of positive urine albumin were reduced in the GSH group compared with the control group, but the results are of questionable significance due to the limited number of cases tested. The results indicate that GSH administration is effective in preventing the side-effects and the possible drop in WBC count associated with adjuvant mitomycin C chemotherapy. It may also be of some value in preventing mitomycin C-induced hepatic and renal abnormalities.

7148 EFFECTS IN RATS OF SODIUM CHLORIDE ON EXPERIMENTAL GASTRIC CANCERS INDUCED BY N-METHYL-N'-NITRO-N-NITROSOGUANIDINE OR 4-NITROQUINOLINE-1-OXIDE.

(E.) Tatematsu, M.; Takahashi, M.; Fukushima, S.; Hananouchi, M.; Chirai, T. (Nagoya City Univ., Medical Sch., 1 Kawasumi, Mizuho-cho, Mizuho-ku Nagoya 467, Japan). *J. Natl. Cancer Inst.* 55(1): 101-106, 1975.

The effects of NaCl (6 g/liter in the drinking water on 1 ml/week by intragastric tube) on gastric carcinomas induced by N-methyl-N'-nitro-N-nitrosoguanidine (MNNG, 50 mg/liter in the drinking water) and 4-nitroquinoline-1-oxide (NQO, 1 mg/week by intragastric tube) were studied in adult male Wistar rats. In some cases, the rats were fed a stock diet containing 10% NaCl. The MNNG and NQO treatments were continued for 20 weeks, and the tumor incidence was determined in all animals surviving more than 40 weeks. In the MNNG-treated rats, most of the tumors developed in the glandular stomach, whereas in the NQO-treated animals, almost all tumors developed in the forestomach. No tumors developed in untreated controls or in the animals given only NaCl in the drinking water and/or diet. The forestomach tumors were all of squamous cell origin; the incidence of such tumors in the animals given NQO plus NaCl in the diet and/or by intragastric tube was greater than in the rats given NQO alone. The incidence of adenocarcinomas in the glandular stomach was also higher in the groups given MNNG plus NaCl than in the animals given MNNG alone; poorly differentiated adenocarcinomas were detected only in the animals treated with MNNG plus NaCl. Some tumors were found in the large and small intestines, liver, pancreas, and omentum

n the MNNG-treated rats, and metastases to the
ymph nodes or liver were seen in some of the car-
inogen-treated rats. No malignant tumors were de-
ected outside the gastrointestinal tract in any
roup. The data indicate that NaCl alone is not car-
inogenic, but that it enhances the carcinogenic
ffects of MNNG and NQO in the rat stomach. NaCl
ppears to enhance the penetration of the carcinogens
ıt probably is not a 'promoter'.

49 EFFECT OF ZOLIMIDINE, A DERIVATIVE OF IMI-
DAZO (1,2-a) PYRIDINE, ON THE GASTRIC MU-
)SA OF PATIENTS WITH GASTRIC DISORDERS. *(E.)* Celli,
; Clementi, F.; Santagostino, C. (Maggiore Hosp.,
lan, Italy). *Curr. Ther. Res.* 18(1):105-123, 1975.

ıe morphology of the gastric mucosa before and after
reatment with zolimidine by endoscopic, histological
ıd ultrastructural analysis of a single mucosal zone
ıs studied. Biopsy specimens were taken from ten
ıtients with various gastric abnormalities under
edical treatment. Tissues were fixed in formalde-
'de, and stained with PAS or uranyl acetate and lead
trate. Studies were made before and after p.o.
lministration of the drug (800 mg/day) for 4 wks. In
ur patients with advanced ulcer the drug produced a
ear surfacing of the ulcer, with disappearance of
ıe subjective symptoms. Histological examination
ıowed satisfactory healing of the tissues. Electron
croscopy revealed a completely normal cellular in-
astructure. The presence of a greater number of
ıcous granules was noted in the apical zone as well
; more frequent exocytosis. In three cases of in-
ammatory and erosive gastropathy, repair of the
sion was obtained, and in one other case there
ıs a return to normality. An effect of the drug
ı the mucosal barrier was demonstrated in all cases.
ıese results demonstrate that the drug does not
oduce intracellular lesions, has mucopoietic
tivity and acts positively on the gastric bar-
er in reproductive, reparative, defensive and
ınctional processes.

50 GASTRIC EMPTYING FOLLOWING VAGOTOMY AND
ANTRECTOMY AND PROXIMAL GASTRIC VAGOTOMY.
.) Kalbasi, H.; Hudson, F. R.; Herring, A.; Moss,
; Glass, H. I.; Spencer, J. (Hammersmith Hosp.,
ndon, England). *Gut* 16(7):509-513, 1975.

e effects of posture, vagotomy and antrectomy, and
oximal gastric vagotomy on the gastric emptying of
standard physiological solid meal (eggs, toast,
tter, jam, milk) labeled with ^{129}Cs were studied
19 patients who had undergone proximal gastric
gotomy and 16 patients who had undergone truncal
gotomy and antrectomy for duodenal ulcer. The
udies were performed 1, 4, 6, and 12 months after
rgery. On completion of the test meal, the sub-
cts were placed in a supine or sitting position
der the gamma camera and data collection was begun
thin 5 min of the end of the meal; the study was
ntinued for 90 min. Gastric emptying was signifi-
ntly slower in the vagotomy plus antrectomy group
month after surgery than in a healthy control group.
e difference was reduced at 4 months, and gastric emptying in the surgery group was normal at 6 months. At no stage did the proximal gastric vagotomy patients differ significantly from the controls in this respect. Symptoms of epigastric fullness were significantly more frequent in the vagotomy plus antrectomy patients than in the proximal vagotomy patients. Gastric emptying was similar in the supine and sitting positions in all groups, but the vagotomy plus antrectomy patients cleared significantly less of the meal in both positions than did the controls; again, the proximal vagotomy patients did not differ significantly from the controls. It is concluded that any differences in gastric emptying patterns which can be attributed to the effect of posture are of small scale and are restricted to particular groups of patients, such as those with rapid emptying patterns. However, future studies should employ the sitting position as this is closer to normal conditions.

7151 THE ROLE OF ACID AND ISCHEMIA IN PRODUCTION OF STRESS ULCERS DURING CANINE HEMORRHAGIC SHOCK. *(E.)* Zinner, M. J.; Turtinen, L.; Gurll, N. J. (Walter Reed Army Medical Center, Washington, D.C. 20012). *Surgery* 77(6):807-816, 1975.

Twenty adult mongrel dogs with an internally drained Heidenhain pouch were divided into three groups (Group 1, ten animals bled to 45 mm Hg mean arterial pressure and exposed to acid through the pouch; Group 2, seven controls; Group 3, three animals bled to a 45 mm Hg mean arterial pressure without acid exposure). The groups were studied for variations in electrical potential difference (PD), aminopyrine clearance, and net H_2O, Na^+, H^+, K^+, and Cl^- flux. PD was measured through a bridge from the femoral vein to the gastric lumen. Aminopyrine was infused as an i.v. dose of 20 mg/kg and maintained at 5 mg/kg/hr. Clearance was measured as an indicator of mucosal blood flow. Acid test solution (80 mM of HCl, 80 mM of NaCl, 1.5 g/l of polyethylene glycol) was instilled in the pouch, left for 30 min, then drained and replaced by a solution lacking the glycol. Total pouch flow decreased from 37 ml/min to 6 ml/min in group 1 while it remained stable (32 ml/min in controls and 24 ml/min after 5 hrs) in group 2. PD in group 1 decreased from 54 mV to 25 mV, while it remained stable at 57 mV in group 2. Na^+ and H^+ flux remained stable in both groups, while Cl^- fell from a control of 56.8 μEq/30 min/100 cc to -11.7 μEq/30 min/100 cc in group 1. K^+ flux increased from 2.3 μEq/30 min/100 cc to 10.5 μEq/30 min/100 cc in group 1 and remained stable in group 2. Nine of ten pouches in group 1 showed superficial erosions by gross examination, while none in the other groups demonstrated lesions. It appears that K^+ flux may reflect loss of mucosal integrity, rather than Na^+ or H^+, and that acid is a necessary component in the pathogenesis of stress ulcer.

STOMACH

Peptic Ulcers

7208 ESOPHAGITIS AND DUODENAL ULCER. *(E.)* de Moraes-Filho, J. P. P.; Zaterka, S.; Pinotti, H. W.; Bettarello, A. (Sao Paulo Sch. Medicine, Sao Paulo, Brazil). *Digestion* 11(5-6):338-346, 1975.

The incidence of reflux esophagitis and the manometric characteristics of the lower esophageal sphincter in 35 male duodenal ulcer patients was investigated. All patients were submitted to radiological examination of the esophagus, esophagoscopy, histologic study, manometric study of the lower sphincter of esophagus, a study of the gastric secretion of HCl, and statistical analysis. No radiological signs of mucosal fold alterations or strictures were observed in any patients. Esophagoscopy showed esophagitis in 12 of 36 patients. Inflammatory histological mucosal alterations were observed in 21 of the patients. The final diagnosis of esophagitis was established by endoscopy and/or histology in 22 patients. Basal and histalog-stimulated secretion was normal in 11 cases; basal was increased but histalog-stimulated secretion was normal in four cases; both basal and histalog-stimulated were increased in 13 cases; and basal was normal but histalog-stimulated secretions were increased in eight cases. There was no significant difference between the mean values of the resting gastroesophageal sphincter pressure and the length of the lower esophageal sphincter of the controls and the different groups (with and without esophagitis, presence or absence of duodenal narrowing, hypersecretion or normal secretion of HCL). The results show that alterations of esophageal mucosa are related neither to the duration of the ulcer disease nor to basal and histalog acid secretion. These findings suggest that esophageal mucosa is sensitive to regurgitated gastric secretion of its acid content. Also, the intensity of the inflammatory reaction was not increased in the patients with longer histories of duodenal ulcers, indicating that a certain balance occurred between aggression and esophageal resistance.

7209 THE STUDY OF INCIDENCE AND CLINICAL SYMPTOMS OF PEPTIC ULCER IN CERTAIN OCCUPATIONAL GROUPS.

(Bul.) Stoianova, Z.; Stancheva, P.; Vlakhov, I. (Inst. Gastroenterology, Sofia, Bulgaria). *Vutr. Boles.* 13(3):70-77, 1974.

The incidence of peptic ulcer was studied in 2,979 female and 999 male workers in different occupational groups. The overall incidence of peptic ulcer was 3.8%; 3.1% in females and 5.8% in males. The incidence was highest in employees of the telephone company (14.2%); the incidence was 6.3% in steel workers, 6% in clothing factory workers, 2.7% in textile factory workers, and 2.3% in rubber factory workers. The age classes 20 to 30 yr, 31 to 40 yr, 41 to 50 yr and over 50 yr accounted for 20.8%, 43.6%, 27.5% and 8.1%, resp., of all cases. Peptic ulcer was localized in the duodenum in 95.3%, and in the stomach in 4.7% of all cases. Melena was established in 12.8%, hematemesis with melena in 2%, and stenosis of the pylorus in 0.7% of all cases. The incidence of neurasthenic syndrome was highest in the occupational groups with the highest incidence of peptic ulcer.

7210 GASTRIN DETERMINATIONS IN SYMPTOMATIC PATIENTS BEFORE AND AFTER STANDARD ULCER OPERATIONS.

(E.) Stremple, J. F.; Elliott, D. W. (Univ. Pittsburgh Sch. Medicine, Pa.). *Arch. Surg.* 110(8):875-879, 1975.

Gastric acid secretion and serum gastrin levels in a wide variety of clinical conditions were compared in 157 subjects without ulcer and 157 patients with either primary or recurrent ulcer. The non-ulcer group included 125 patients with gastritis, reflux esophagitis, anephria, short gut syndrome, primary hyperparathyroidism and a gastrin-producing adenoma, and 32 normal subjects. Neither the mean fasting nor the mean postprandial serum gastrin levels in patient controls differed from these values in normal controls. There was no significant difference between basal or maximum acid output in normal controls (2.2 and 16.8 mEq/hr, resp.) compared to patients with gastric ulcer (2.1 and 19.5 mEq/hr, resp.). Patients with duodenal ulcers had markedly elevated mean basal and maximum acid outputs (5.2 and 34.1 mEq/hr, resp.) compared to normals and gastric ulcer patients. Fasting mean serum gastrin levels were 45 pg/ml in normal subjects and 43 pg/ml in duodenal ulcer patients compared to postprandial values of 75 and 77 pg/ml, resp. These differences were not significant. Patients after vagotomy and Billroth I or II operations had lower basal and maximum acid outputs after surgery than normals. Patients after vagotomy and Billroth II procedures had elevated fasting serum gastrin levels that decreased postprandially. Patients with recurrent ulcer after incomplete vagotomy and gastric resection had high gastric acid secretion and normal serum gastrin levels. Patients with recurrent ulcer after complete vagotomy and gastric resection with retained antrum had both high acid output and high fasting and postprandial serum gastrin levels. Basal acid outputs and serum gastrin levels were even more elevated in patients with the Zollinger-Ellison syndrome. These results demonstrate that basic gastric acid secretory studies in combination with serum gastrin determinations can aid in the diagnosis of the Zollinger-Ellison syndrome and recurrent ulcers.

7211 BLOOD FLOW DISTRIBUTION IN THE STOMACH OF CATS WITH GASTRIC ULCER.

(E.) Skarstein, A.; Svanes, K. (Dep. General Surgery, Univ. Bergen, Norway). *Scand. J. Gastroenterol.* 10(4):339-345, 1975.

The blood flow distribution in the stomach of cats with a one-week gastric ulcer was investigated. Ulcer was induced in the anterior wall of the antrum by a subserous injection of 0.3 ml of a 20% acetic acid solution; controls were laparotomized only. Carbonized microspheres 15 ± 5μ in diameter and labeled with ^{169}Yb were used to measure blood flow in different regions and layers of the stomach. Approximately 2-3 million microspheres were injected into the left ventricle of the heart. Simultaneously a blood sample was drawn from the distal aorta at a flow of 1 ml/min. Standardized tissue samples were punched from the lesser curvature and the anterior and posterior walls of the antrum, corpus and fundus. In each sample the mucosa was separated from the muscularis. The radioactivity of blood and tissue samples was determined, and the blood flow was calculated for each tissue sample. Three groups of animals were examined: anaesthetized control animals; animals laparotomized one wk before examination, and animals with a one-week ulcer. In the control animals the blood flow was the same in corresponding regions of the anterior and posterior walls of the stomach. The flow was slightly lower in the antrum than the fundus. The flow was similar in the different regions of the muscularis. The muscularis flow was markedly lower than the mucosa flow. In the laparotomized animals, the blood flow was increased in the muscularis of the corpus. In the ulcer animals, the mucosa flow was increased in the anterior wall of the antrum, and the muscularis flow was increased in the antrum and the anterior wall of the corpus. The results strongly suggest that gastrointestinal surgery with rough handling of the intestines is associated with marked circulatory changes in the abdominal organs.

7212 SERUM GROUP I PEPSINOGENS BY RADIOIMMUNOASSAY IN CONTROL SUBJECTS AND PATIENTS WITH PEPTIC ULCER. *(E.)* Samloff, M.; Liebman, W. M.; Panitch, N. M. (Harbor General Hosp., 1000 West Carson St., Torrance, Calif. 90509). *Gastroenterology* 69(1):83-90, 1975.

Serum group I pepsinogen levels were compared in 300 healthy controls, 389 patients without peptic ulcer, 136 patients with peptic ulcer, and seven with the Zollinger-Ellison syndrome. The mean serum group I pepsinogen levels in healthy and hospital controls were 110.6 and 100.0 ng/ml, resp., and in both groups were significantly higher in males than in females. Values for approximately 90% of the healthy controls ranged from 50 to 175 ng/ml, and this was determined as normal. The mean serum group I pepsinogen level was 410.6 ng/ml in 55 cases with serum urea nitrogen over 21 ng/100 ml. A high value was found in 39 (70.9%) of these patients. The mean serum group I pepsinogen level in 37 patients with chronic alcoholism was 73.4 ng/ml; in 46 cases with gastric ulcer, 116.6 ng/ml; in 18 with prepyloric ulcer, 179.4 ng/ml; in 13 with both duodenal and gastric ulcer, 177.2 ng/ml; and in 77 with duodenal ulcer, 221.3 ng/ml, median level 203.0 ng/ml. None of the patients in this last group had a low value, and 49 (63.6%) had levels over 175 ng/ml. These patients had significantly higher ($P < 0.001$) mean levels of serum group I pepsinogen than healthy male controls. Serum group I pepsinogen values ranged from 315 to 921 ng/ml (mean, 503.9 ng/ml) in patients with the Zollinger-Ellison syndrome. These data indicate that in comparison to healthy controls, patients with prepyloric ulcer, duodenal ulcer and the Zollinger-Ellison syndrome have significantly increased levels of serum group I pepsinogen, that patients with gastric ulcer have comparable values, and that those with chronic alcoholism have significantly decreased levels.

7213 STUDIES ON THE BINDING OF AMYLOPECTIN SULFATE WITH GASTRIC MUCIN. *(E.)* Kim, Y. S.; Bella, A.; Whitehead, J. S.; Isaacs, R.; Remer, L. (Veterans Administration Hosp., 4150 Clement St., San Francisco, Calif. 94121). *Gastroenterology* 69(1):138-145, 1975.

Binding of canine gastric mucin to amylopectin sulfate gel was studied by chemical assay for reducing sugars and by column chromatography. Hydrated amylopectin sulfate gel (4 ml) was washed with 0.1 M citric acid-phosphate buffer (pH 7.0), and centrifuged at 48000 x *g* for 20 min. One ml of 0.8 mg/ml of mucin solution was added, the pH was adjusted in the range from 3 to 7 and the mixture placed in a 25 C bath for 2 hr, then centrifuged at 48000 x *g* for 20 min. The supernatant was decanted, filtered and assayed for reducing sugars as the determination of unbound mucin. Pasteur pipettes lined with glass wool were saturated with amylopectin sulfate and 0.02 M citrate-phosphate buffer (pH 3). The effluent was measured and assayed for neutral sugars and pH. Mucin (10-20 mg/ml) was incubated with aqueous amylopectin sulfate (10-50 mg/ml) for 30 min at 25 C. Aliquots of 25 µl were used for electrophoresis at various pH values. At pH 3 and pH 4, 65 to 85% of the mucin fraction was bound to the gel, while at pH 7, only 35 to 40% was bound. On column chromatography, one mucin fraction did not bind, while a second eluted at pH 4.5. When pepsin was applied to the column, it eluted upon application, except at pH 2. The mucin bands which remained at the origin on electrophoresis were bound by amylopectin sulfate, while those which migrated did not bind. It appears that there is little difference between the fractions which bound to amylopectin sulfate and those which failed to do so. It is suggested that pepsin-amylopectin sulfate interaction occurs only in states of excessive acid secretion.

7214 INHIBITION OF GASTRIC ACID SECRETION BY CIMETIDINE IN PATIENTS WITH DUODENAL ULCER. *(E.)* Henn, R. M.; Isenberg, J. I.; Maxwell, V.; Sturdevant, R. A. L. (Veterans Admin. Wadsworth Hosp. Center, Los Angeles, Calif.). *N. Engl. J. Med.* 293 (8):371-375, 1975.

The effect of cimetidine, a nonthiourea-containing H_2-receptor antagonist, on basal and meal-stimulated gastric acid secretion was studied in seven males with duodenal ulcer (age range, 36-63 yr). The effects of cimetidine and an optimally effective dose of an anticholinergic, propantheline bromide, on meal-stimulated gastric acid secretion were compared. Eight cimetidine tests (four basal and four meal-stimulated) were performed on separate days, in random order, and in double-blind fashion. Each dose of cimetidine markedly decreased gastric acid secretion as compared with either basal or acid secretion after placebo; mean gastric acid content of stomach aspirate 1 hr after placebo and cimetidine doses of 100, 200 and 300 mg were 0.9, 0.3, 0.4 and 0.1 mEq/hr, resp. Three hundred mg of cimetidine decreased mean basal acid secretion to almost zero for 5 hr. The increasing doses of cimetidine produced graded increases in mean blood concentrations. Cimetidine and optimal propentheline bromide each decreased meal-stimulated acid secretion; however, 300 mg of cimetidine produced greater mean secretory inhibition which lasted through three hr. Inhibition of gastric acid output was positively correlated with blood cimetidine concentrations. No effect on serum gastrin response to a peptone meal or evidence of clinical or biochemical abnormalities in serial acute tests were observed following cimetidine ingestion. Thus, cimetidine was a potent inhibitor of both basal and meal-stimulated gastric acid secretion, and its effects were dose-related. Because of its effectiveness in inhibiting gastric acid secretion, superior potency to anticholinergics, and the lack of acute side effects, cimetidine is suggested as a potential therapeutic agent for the treatment of patients with peptic ulcer disease provided no toxicity appears with chronic testing.

7215 A COMPARISON OF THE ACID NEUTRALIZING EFFECTS OF A COMBINATION OF ANTACID PLUS OXETHAZAINE (OXAINE M) COMPARED TO ANTACID ALONE (ALUDROX) IN DUODENAL ULCER PATIENTS.

(E.) Novaes, C. C.; Richards, D. J.; Davis, G. R. (Santa Helena Hosp., Recife, Pernambuco, Brazil). *Curr. Ther. Res.* 18(1):124-131, 1975.

The effects of antacid and of antacid combined with oxethazaine on the development of gastric alkalinity and recovery of acidity were studied in 20 duodenal ulcer patients under maximal stimulation by a histamine analogue. Each patient received antacid/oxethazaine and antacid on successive days. The pH of the gastric milieu was continuously measured using a radiotelemetry capsule which was swallowed and positioned in the most dependent portion of the stomach. The histamine analogue was administered s.c. at a dose of 1.7 mg/kg; 60 min later, the antacid medications were administered by gastric tube. Anacidity was defined as a gastric pH of 3.5 or higher. Since the baseline pH values in the duodenal ulcer patients were quite low, the histamine analogue often produced little or no stimulation of gastric acidity. The mean peak pH produced by the oxethazaine/antacid mediation (5.29) was significantly greater than that produced by the antacid alone (4.5), and the mean duration of anacidity was longer after the oxethazaine combination (4.42 min) than after the antacid alone (2.74). The mean overall time period from medication administration to peak pH was nearly the same for both medications, as was the time required for return to pH 3.5 after attainment of the peak value. The oxethazaine/antacid effect could have been the result of an oxethazaine-induced increase in gastric pH, decrease in gastric acid secretion, and decrease in gastrin level.

7216 SERUM GASTRIN RESPONSE TO FOOD STIMULATION AND GASTRIC ACID SECRETION IN MALE PATIENTS WITH DUODENAL ULCER.

(E.) Gedde-Dahl, D. (Rikshospitalet, Oslo, Norway). *Gut* 16(1):189-191, 1975.

The gastrin response to a test meal was recorded in nine male patients with duodenal ulcer, related to their gastric acid secretion before and after stimulation with pentagastrin, and compared with the findings in male controls. The serum gastrin concentrations were determined by radioimmunoassay, and gastric secretion of acid was determined before and after stimulation with 6 μg pentagastrin/kg given s.c. The patterns of gastrin response was biphasic, with an early maximum of the first peak in the patients *versus* a monophasic response with a maximum in the second hr in the controls. The mean value of basal acid outputs (BAO), both per subject and per kg, was significantly higher in the duodenal ulcer groups than in the controls; the mean values for maximal acid outputs (MAO) was not significantly different. There was a positive correlation between weight-adjusted BAO and MAO in controls, but not in the patients. The mean fasting serum gastrin concentration in the duodenal ulcer group, 109 ± 24.5 pg/ml, was significantly higher than in the control group, 42 ± 5.5 pg/ml. BAO values in the duodenal ulcer group correlated positively with the fasting serum gastrin concentration, total gastrin output, and the integrated gastrin response. The results indicate that the acid inhibitory feedback mechanism may be impaired in patients with duodenal ulcer disease.

7217 STIMULATION OF HUMAN PEPSIN OUTPUT BY TOPICAL HYDROCHLORIC ACID.

(E.) Bynum, T. E.; Johnson, L. R. (Baylor Coll. Medicine, Houston, Tex.). *Dig. Dis.* 20(7):607-612, 1975.

The presence in man of an acid-sensitive reflex similar to that demonstrated in the dog was studied for its relation to ulcer disease. Pepsin output and concentration were measured from the stomach of healthy subjects during irrigation with phosphate buffer or 0.2 N HCl during twelve 15-min periods. There was a highly significant 4-fold increase in pepsin output and a three-fold increase in pepsin concentration after introduction of 0.2 N HCl. Secretion of pepsin increased immediately in the first period and remained at a high sustained level for the entire hour of perfusion. Pepsin output fell to control levels immediately following reintroduction of phosphate buffer. Pepsin outputs after 0.15 N HCl were lower than after the higher concentration, but this difference was not statistically significant. These results indicate that pepsin output increases significantly during acidification of the gastric mucosa in man, and may play a significant pathogenic role in ulcer production.

7218 RELIEF OF DUODENAL ULCER SYMPTOMS BY ORAL METIAMIDE.

(E.) Pounder, R. E.; Williams, J. G.; Milton-Thompson, G. J.; Misiewicz, J. J. (Central Middlesex Hosp., London, NW10 7NS, England). *Br. Med. J.* 2(5966):307-309, 1975.

A double-blind clinical trial of oral metiamide and a placebo was performed on 30 duodenal ulcer patients to determine its effect on symptoms and antacid consumption in this disease. Treatment consisted of 200-mg metiamide tablets, 3 times/day after meals and 400 mg at night (15 patients) or the same amount of lactose-placebo (15). All subjects were followed at least 5 weeks, and 23 were treated for 8 weeks. Metiamide treatment produced a significant reduction of both day and night pain, and patients on placebo experienced more severe pain than those receiving metiamide. Patients on metiamide consumed significantly less antacid during weeks 2, 3 and 5 than controls. There were no adverse effects reported by any patient. Mild side effects (sedation, headache and dizziness) were reported by ten patients on metiamide and five controls, but these effects were not severe. It is suggested that treatment with an H_2-receptor antagonist produces an early remission of duodenal ulcer.

7219 ASPECTS OF THE EFFECT OF METIAMIDE ON PENTAGASTRIN-STIMULATED AND BASAL GASTRIC SECRETION OF ACID AND PEPSIN IN MAN.

(E.) Thjodleifsson, B.; Wormsley, K. G. (Dept. Therapeutics, Univ. Dundee, Dundee, Scotland). *Gut* 16(7):501-508, 1975.

The pharmacological effects of metiamide on gastric acid and pepsin secretory inhibition were studied in 13 patients with duodenal (DU) and three with gastric ulcer (GU) to provide a basis for metiamide dose requirements in peptic ulcer treatment. The effect of metiamide on the response to a range of pentagastrin doses (0.05, 0.2, 1.0, and 4.0 µg/kg/hr for 60 min) in three normal subjects was determined, as was the interaction of metiamide and atropine on prolonged basal secretion. Pentagastrin infusion followed one of two dose schedules: i.v. bolus of 75 mg (Schedule I) or 20 mg (Schedule II), followed by continuous infusion of 30 mg during 60 min. Metiamide was injected, i.v., 10 min before the start and during the course of pentagastrin infusion. Gastric secretion of acid and pepsin was inhibited more in patients with GU than DU and gastric acid secretory inhibition was significantly greater than pepsin inhibition for all concentrations of metiamide. The mean calculated maximal response to pentagastrin was progressively depressed from 16.2 (control value) to 8.9 mM/30 min (schedule II) and further reduced to 6.1 mM/30 min (schedule I). The ED_{50} of pentagastrin increased from 0.15 to 0.32 µg/kg/hr (II) and to 0.90 µg/kg/hr (I). Thus, metiamide inhibited both the maximal secretory response attainable with pentagastrin and decreased the sensitivity to pentagastrin. Atropine augmented and prolonged the action of metiamide. The powerful inhibitory action of metiamide on gastric secretion may have therapeutic value in treatment of diseases in which acid and pepsin secretion play an etiological role. However, the degree of secretory inhibition necessary to permit healing of mucosal lesions remains unknown.

7220 GASTRIC SECRETORY INHIBITION BY TWO 16-METHYLATED ANALOGS OF PROSTAGLANDIN E_2 GIVEN INTRAGASTRICALLY TO PATIENTS WITH DUODENAL ULCER DISEASE.

(E.) Nylander, B.; Andersson, S. (Dep. Internal Medicine, Karolinska Hosp., Stockholm, Sweden). *Gut* 16(1):217-220, 1975.

The effects of two methylated analogs of prostaglandin E_2 (PGE_2), 16,16-dimethyl PGE_2 and its methyl ester, on gastric acid and pepsin secretion were studied in five ulcer patients. The gastric residuum was removed twice and radiovitamin B_{12} was used as an indicator for the recovery of gastric juice. Gastric juice was collected continuously in 15-min samples. The mean control secretory rate of the five ulcer patients was 45 mEq/hr compared with 25 mEq/hr for controls. With 80 µg of 16,16-diMe PGE_2 the median pH of residuum I was 1.6 and that of residuum II, 5.9, indicating inhibition of basal gastric secretion. Concentrations of 80 and 140 µg of both compounds gave a dose-dependent decrease in acid output. It was necessary to give 140 µg of each analog to reach about the median effective dose. The mean values of pepsin output and pepsin concentration were decreased following administration of PGE_2, but the individual results varied. The results show that these two prostaglandin analogs inhibit gastric acid secretion in duodenal ulcer patients in a dose-dependent fashion and that the inhibition is mainly due to a reduction of volume, contributing to about 60% of the overall reduction of acid output.

7221 EFFECT OF SEROTONIN AND ENDOTOXIN ON ACUTE GASTRIC STRESS ULCERATION IN CONVENTIONAL AND GERM-FREE RATS.

(E.) Batson, R. C.; Greenberg, P. H.; Nance, F. C. (Louisiana State Univ. Sch. Medicine, New Orleans, La.). *Surg. Forum* 24:426-428, 1973.

The effects of endotoxin and 5-hydroxytryptamine on conventional and germ-free mice subjected to restraint stress were studied. After fasting, 80 conventional and 40 germ-free mice were randomly divided into four groups, receiving i.p. injections of: 5-hydroxytryptamine (10 mg/kg); endotoxin (4 mg/kg); endotoxin plus 5-hydroxytryptamine, or saline. Animals were sacrificed 24 hr after being restrained by stapling between two pieces of screen wire. Restrained, germ-free mice had significantly fewer ulcers than conventional mice. Endotoxin alone had no effect on ulceration in either strain. Serotonin resulted in an increase in both the incidence and severity of ulcerations in both strains. Endotoxin and serotonin in combination induced a greater number of ulcers than serotonin alone. Neither humoral factor increased the number of ulcers in germ-free mice to the level observed in conventional controls. It is concluded that the germ-free state gives significant protection from restraint-induced ulceration.

7222 GASTRIC ACID AND PEPSIN SECRETION IN PATIENTS UNDERGOING INTERMITTENT HEMODIALYSIS.

(Ger.) Pointner, H.; Flegel, U.; Schmidt, P.; Zazgornik, J.; Kopsa, H. (Med. Clin. I, Univ. Vienna, Austria). *Wein Klin. Wochenschr.* 86(22):693-696, 1974.

To evaluate the high incidence of gastrointestinal disturbances in uremia, gastric acid secretion and pepsin secretion were measured in 15 uremic patients undergoing biweekly hemodialysis. Eight of the patients had radiologically confirmed peptic ulcers and two had duodenal irritation without overt ulceration. One day before dialysis, fasting gastric juice was obtained in three 20 min periods (basal) and secretion was stimulated by pentagastrin (6 µg/kg body weight, s.c.). Gastric juice was obtained in six 15 min periods and the peak output was calculated from the two highest 15 min periods. The volume of the juice was measured. HCl concentration was measured by titration; pepsin activity was determined by a slight modification of the Anson and Mirsky method and expressed in mg of tyrosine. Mean basal acid output for all 15 patients was 3.9 mEq/hr; peak acid output was 25.3 mEq/hr; basal pepsin output was 20.2 mg tyrosine/hr; peak pepsin output was 71.4 mg tyrosine/hr. Gastric acid values from 30 normal individuals and pepsin values from five normal individuals did not differ from the values in the uremic patients. It is concluded that a multifactorial etiology must be assumed for ulceration in the cases studied. There was great variation of values between all patients but no correlation of acid or pepsin values to gastrointestinal disturbances. Mean blood urea nitrogen was 91.1 mg %, mean serum creatinine was 13.5 mg %, mean serum Ca was 9.2 mg % in the uremic patients. It is concluded that in uremic patients neither gastric acid secretion nor pepsin secretion is responsible for the high incidence of peptic ulceration and other gastrointestinal distrubances.

7223 BONE MINERAL AFTER PARTIAL GASTRECTOMY II.

(E.) Aukee, S.; Alhava, E. M.; Karjalainen, P. (Univ. Central Hosp., Kuopio, 70210 Kuopio 21, Finland). *Gut* 16(1):165-169, 1975.

Bone mineral measurements by the Americium-241 gamma ray attenuation method were performed on the cancellous bone of the left distal radius of three groups of ulcer patients (30 preoperative patients in Group I; 70 patients 3.3-8.5 yr post-1/3 gastrectomy and Billroth I reconstruction with selective vagotomy in 36 comprising Group II; 60 patients 15-18 yr post-2/3 gastrectomy and Billroth II reconstruction forming Group III) to study the mineral density of bone postoperatively. Group I did not differ significantly from controls (0.302 g/cc *versus* 0.301 in controls), nor did males in Group II (0.281 g/cc *versus* 0.289 in controls). Females in Group II showed significant decreases in mineral density (0.232 g/cc *versus* 0.260 in controls), as did all patients in group III (0.255 *versus* 0.289 in males and 0.230 *versus* 0.254 in females). When corrected for known diseases affecting bone metabolism, the decreased density in group III males was 9.3% and 9.4% in females. The mineral density of bone was decreased after ulcer surgery by approximately 10%, but this decrease did not appear to endanger the patients' health or well-being.

7224 DECREASE IN GASTRIC SECRETION DURING THE FIRST THREE MONTHS AFTER PROXIMAL GASTRIC VAGOTOMY IN DUODENAL ULCER PATIENTS.

(E.) Roland, M.; Berstad, A.; Liavag, I. (Aker Univ. Hosp., Oslo, Norway). *Scand. J. Gastroenterol.* 10(4):363-367, 1975.

Gastric secretion was stimulated by i.v. infusion of pentagastrin (15 μg/kg/hr) before and 10 and 90 days after proximal gastric vagotomy in 16 duodenal ulcer patients. Postoperatively, pentagastrin (15 μg/kg/hr) was also given in combination with carbacholine (2 μg/kg/hr). Mean acid output in response to pentagastrin alone was reduced by 48% and 64% at 10 and 90 days, resp., after vagotomy. Mean pentagastrin stimulated acid output and volume of gastric juice was significantly higher at 10 days than at 90 days after the operation. Mean pepsin output decreased also, but the decrease was not statistically significant. There was no significant effect of carbacholine on pentagastrin-stimulated acid output either at 10 or 90 days. Carbacholine increased pentagastrin stimulated volume of gastric juice significantly at 19 but not 90 days postoperatively. The effect of carbacholine on pentagastrin-stimulated pepsin output was significant both 10 and 90 days after the vagotomy. Pepsin output in response to pentagastrin plus carbacholine 10 days after the operation was not significantly different from preoperative values. At 10 days postoperatively the increase in pentagastrin stimulated volume of gastric juice by carbacholine was significantly greater than at 90 days. The corresponding differences of acid and pepsin outputs were not significant. It is concluded that the preoperative secretion of acid cannot be restored by a maximal dose of pentagastrin or by pentagastrin in combination with carbacholine either 10 or 90 days after proximal gastric vagotomy. The results show a significant decrease in maximal acid output from 10-90 days after vagotomy.

7225 LONG TERM EFFECT OF HIGHLY SELECTIVE VAGOTOMY ON BASAL AND MAXIMAL ACID OUTPUT IN MAN.

(E.) Greenall, M. J.; Lyndon, P. J.; Goligher, J. C.; Jonston, D. (General Infirmary, Leeds, England). *Gastroenterology* 68(6):1421-1425, 1975.

Basal acid output (BAO) and maximal acid output (MAO) were measured five yr after highly selective vagotomy (HSV) in 21 patients who had previously undergone serial testing of BAO and MAO for up to two yr after HSV. Gastric secretion was aspirated by continuous suction for a basal period of one hr and for one hr after the i.m. injection of 6 μg/kg of pentagastrin before operation and 10 μg/kg after operation. Stimulated acid output was expressed both as peak acid output to pentagastrin (PAO^{pg}) which was peak 30-min acid output multiplied by two, and as total hour output, the acid output in the hour after the pentagastrin injection. BAO was the total amount of acid secreted during the basal hour. BAO decreased from a mean of 1.7 mEq/hr at one yr after HSV to 1.4 mEq/hr at five yr after HSV (not significant). The mean reduction in BAO at five yr, compared with the preoperative BAO of 8.4 mEq/hr, was 79%. The mean peak acid response to PAO^{pg}, compared with the preoperative PAO^{pg} of 43 mEq/hr, was 51% at one year and 48% at five yr. Inasmuch as acid outputs seem unlikely to increase further after five yr, it is concluded that HSV produces a permanent reduction of about 80% in basal acid output and 50% in maximal acid output.

7226 A HISTOLOGICAL STUDY OF GASTRIC MUCOSA BEFORE AND AFTER PROXIMAL GASTRIC VAGOTOMY IN DUODENAL ULCER PATIENTS.

(E.) Roland, M.; Berstad, A.; Liavag, I. (Aker Univ. Hosp., Oslo, Norway). *Gut* 16(1):181-186, 1975.

Suction biopsies were taken from the body of the stomach in 29 duodenal ulcer patients before and after proximal gastric vagotomy (PGV) in order to study the degree of gastritis, the gastric mucosal thickness and the number of parietal cells/unit area. All patients had a negative insulin test three month after the operation. A pentagastrin test was performed within two weeks before and 3 and 12 months after PGV. Three months after PGV, basal and pentagastrin stimulated acid secretion were reduced by 82 and 64% of preoperative values, resp. Twelve months after the operation the corresponding figures were 63 and 56%. There was a similar acid reduction in patients with and without gastritis. The number of patients with atrophic gastritis increased from three before the operation to 11 three months after PGV. There was no further increase from three to 12 months postoperatively. The average thickness of gastric mucosa and the mean number of parietal cells/unit area before PGV did not show any significant change three months and one yr after the operation. There was a significant correlation between the number of parietal cells/unit area and maximal acid output before but not after PGV. Acid output/parietal cell was higher before PGV, suggesting that the decrease in gastric secretion after PGV cannot be attributed to the development of gastritis or reduction of parietal cell number.

7227 THE EFFECT OF ATROPINE AND VAGOTOMY ON THE SECRETION OF GASTRIC INTRINSIC FACTOR (IF) IN MAN. *(E.)* Vatn, M. H.; Semb, L. S.; Schrumpf, E. (Ulleval Univ. Hosp., Oslo 1, Norway). *Scand. J. Gastroenterol.* 10:59-64, 1975.

Concentrations of gastric intrinsic factor (IF), acid and pepsin in gastric secretions of eight duodenal ulcer patients treated with atropine (1 mg, i.v.) and seven patients successfully treated by proximal gastric vagotomy were compared during basal secretion and after stimulation by s.c. pentagastrin (6 mg/kg). Atropine was administered alone or coincidentally with pentagastrin. IF concentration was estimated by the hemoglobin-coated charcoal method. Atropine reduced the pentagastrin-stimulated increase in volume of gastric juice (208 ml, no atropine; 125 ml, with atropine), acid output (no atropine, 32.2 mEq; with atropine, 20.2 mEq), pepsin output (no atropine, 90.3 mg; with atropine, 22.8 mg), and IF output (10255 U *versus* 5364 with atropine), while concentrations of each did not differ significantly with atropine (acid, 119 mEq/l; pepsin, 453 mg/l; IF, 44 μ/l) or without atropine (acid, 119 mEq/l; pepsin, 538 mg/l; IF, 45 μ/l). Atropine reduced the volume of gastric juice (141 ml, basal, *versus* 52 ml, basal with atropine) and the acid concentration (70 mEq/l *versus* 52 mEq/l) and pepsin concentration (701 mg/l *versus* 547 mg/l) in gastric juice, while not altering the IF concentration in gastric juice (56 *versus* 49 μ/ml). Vagotomy reduced the concentration of acid (52 *versus* 29 mEq/l), while not altering the concentration of IF (42 *versus* 36 μ/ml) in gastric juice. The secretion of IF, acid and pepsin stimulated by pentagastrin was decreased by atropine, secondary to a reduction in the volume of gastric juice. Basal secretion of IF and IF concentration in gastric juice were unchanged by "medical" or surgical vagotomy.

SMALL INTESTINE

7293 ACUTE DUODENITIS AND DUODENAL ULCERATION AFTER BURNS. CLINICAL AND PATHOLOGICAL CHARACTERISTICS. *(E.)* Czaja, A. J.; McAlhany, J. C.; Pruitt, Jr., B. A. (Brooke Army Med. Cent., Fort Sam Houston, Tex.). *JAMA* 232(6):621-624, 1975.

The clinical and pathological characteristics of Curling ulcer were defined by early and serial endoscopic examinations of the duodenum in 37 burned patients. Only two of these were women; the subjects ranged in age from 16 to 74 yr, with burn sizes ranging from 23% to 96% of the total body surface; mortality was 75.6%. Of 58 endoscopic procedures performed, there were no complications; 24 patients were studied within 72 hr after the burn and 13, 4-30 days later. Duodenal disease was present in 27 patients and occurred only in those with burns involving more than 38% of the total body surface. Erosive duodenitis was seen to occur in some patients within 12 hr after injury and was usually associated with acute gastric disease. Isolated duodenitis occurred only in patients with pancreatitis. Contrast roentgenograms did not reliably show the superficial mucosal disease. Duodenal ulcerations were present in 12 patients and developed on a background of diffuse superficial mucosal injury. Other complications in the patients' postburn course influenced disease progression. Hemorrhage occurred in six patients with duodenal disease, usually originating from a posterior duodenal ulcer. Uncomplicated ulcers invariably healed within 5 weeks after diagnosis. It is suggested that the goals of future investigations should be to define and control the factors that influence the progression or resolution of early superficial injury.

7294 MESENTERIC CYSTS: A CAUSE OF SMALL BOWEL OBSTRUCTION IN CHILDREN. *(E.)* Christensen, J. A.; Fuller, J. W.; Hallock, J. A.; Sherman, R. T. (Coll. Med., Univ. South Florida, Tampa). *Am. Surg.* 41(6):352-354, 1975.

A case of complete mechanical small bowel obstruction secondary to a mesenteric cyst in a 30-month-old girl is reported. The patient presented with a 4-day history of constipation, abdominal pain, and vomiting. Her abdomen was moderately distended and X-rays showed multiple air fluid levels and loops of distended small bowel. The child's WBC was 11,000 mm^3 with 73% polymorphonuclear cells and 3% bands. Her hemoglobin was 12 g% and her hematocrit was 36 mm. Laparotomy revealed marked dilation of the proximal small bowel and volvulus of the ileum around a cyst in the pelvis. A multiloculated mesenteric cyst, containing chylous fluid and involving mesentery of the ileum, was identified. Attempts to enucleate the cyst were unsuccessful and accordingly the small bowel and mesentery involved by the cyst were resected. The patient was discharged on the 7th postoperative day. Since 1964, 13 patients under 10 yr with mesenteric cysts have been reported in the English literature. Ten patients presented with an abdominal mass or distention. Chronic abdominal pain was present in 3 and acute pain in 5. X-rays including contrast studies were helpful in 5 cases. Bowel obstruction was noted in 4 cases. The rectosigmoid mesentery is difficult to resect and if enucleation cannot be done, internal drainage into the free peritoneal cavity is the procedure of choice.

7295 GASTRIC SECRETION AND SERUM GASTRIN IN HUMAN SMALL BOWEL BYPASS.

(Eng.) Coyle, J. J.; Varco, R. L.; Buchwald, H. (Dept. Surgery, Univ. Minnesota, Minneapolis, Minn. 55455). *Arch. Surg.* 110(8):1036-1038, 1975.

The effect of massive small bowel bypass on basal and peak stimulated acid output and on the fasting serum gastrin level in man was studied. Jejunoileal bypass for massive obesity was performed on 37 patients. Gastric secretory studies were performed preoperatively and about 1 yr postoperatively. These patients underwent exclusion of the small bowel from 40 cm distal to the ligament of Treitz to 4 cm proximal to the ileocecal valve. A separate group of 26 patients who had undergone the same operation for obesity 2 yr prior to this time had fasting serum samples collected for measurement of gastrin levels. In the group of 37 patients, the average decrease in body weight was 43.4 kg during this first postoperative yr. The basal acid output stood at 1.95 mEq/hr preoperatively and 2.45 mEq/hr postoperatively. Peak stimulated acid output stood preoperatively at 14.80 mEq/30 min and 16.65 mEq/30 min postoperatively. Of the 37 patients, 24 showed increases in peak stimulated acid output (greater than 2 mEq/30 min in 16 patients). Clinically, 36 of these patients were asymptomatic with respect to possible gastric-related complaints. This study demonstrates no change in fasting serum gastrin levels of patients with massive intestinal bypass. It is suggested that the bypassed segment of the intestine may protect patients against fasting hypergastrinemia. However, the hormonal response to meals must be investigated in humans with small bowel bypass. The small, but statistically significant, increase in peak stimulated acid output was noted, but no clinical significance could be attached to it.

7296 LONG TERM CHANGES IN TOTAL BODY WATER, TOTAL EXCHANGEABLE SODIUM AND TOTAL BODY POTASSIUM BEFORE AND AFTER ILEOSTOMY.

(Eng.) Hill, G. L.; Goligher, J. C.; Smith, A. H.; Mair, W. S. J. (General Infirmary, Leeds, England). *Br. J. Surg.* 62(7):524-527, 1975.

Total body water, total body potassium and total exchangeable sodium were measured in ten patients (6 men and 4 women, aged 26-63 yr) with inflammatory bowel disease. The measurements were made before and 6 mo after a permanent ileostomy was established. All patients underwent elective surgery, but all were malnourished when the first measurement was made before surgery. Six mo after the operation, all patients were in good health and their ileostomies were functioning normally. As a group they had gained 6.8 kg in body weight and 372 mEq in total body potassium over this period of time. In calculating the normal total body water before surgery, a deficit of 12.4% for the group was found. This deficit was still present in 11.1% 6 mo after operation. The concentration of exchangeable sodium in the body water fell from an abnormally high level before surgery to within the normal range 6 mo later. From these data it is obvious that deficits in total body water occurring before surgery are not repaired in the 6 mo after the establishment of a well-functioning ileostomy. A reduction of total exchangeable sodium was still present in patients with an ileostomy who were otherwise well. It is suggested that patients with intractable inflammatory bowel disease achieve good nutrition and normal body composition before this type of surgery is performed.

7297 QUALITY OF LIFE: THE CONTINENT ILEOSTOMY.

(E.) King, S. A. (Stamford Hosp., Stamford, Conn.). *Ann. Surg.* 182(1):29-32, 1975.

Continent ileostomies (internal ileal reservoir or Kock Pouch) were constructed in 10 patients (five men and five women, aged 19-49 yr) suffering from ulcerative colitis (six), colitis (one), toxic megacolon (two), and mucosal disease (one). Of these 10 patients, nine were converted from a standard ileostomy with an external appliance to the continent ileostomy for various reasons. Of the nine, eight were converted successfully. Two patients suffered subsequent loss of continence due to reduction or intussusception of the nipple valve. In one of these two the adequacy of the pouch size seems to have a bearing on maintaining a satisfactory level of continence. The second patient is very much inconvenienced by varying levels of continence which are in part due to slow development of pouch size. Of three Type A reservoirs used, two have a satisfactory level of continence, albeit without full continence of flatus. The total failure is due to adhesions. Of seven Type C reservoirs, five are fully continent and have been so since surgery. The other two Type C patients became incontinent four months following surgery. A modification of the formation of the nipple by offsetting the mesentery to allow more complete suture placement may help in Type C reservoir patients. A dramatic improvement in life style was attested to by seven of the 10 patients, thus illustrating the high level of patient satisfaction with a continent ileostomy. The most common postoperative complication in this series was small bowel obstruction, occurring in three of the 10 patients. Due to episodes of obstruction related to peanuts, sesame seeds, and kernel corn, it is recommended that these patients irrigate their pouches weekly with tap water until clear. Two pouch suture line leaks occurred in these 10 patients, one of the major operative risk elements with this procedure. With experience, the internal reservoir procedure is probably as safe as most other major operative procedures. The elimination of the need for an external appliance, thus allowing a more normal life style, may encourage earlier operative intervention in patients with ulcerative colitis with a concomitant reduction in morbidity and mortality.

7298 CHANGES IN CANINE GASTRIC ACID OUTPUT AND SERUM GASTRIN LEVELS FOLLOWING MASSIVE SMALL INTESTINAL RESECTION. *(E.)* Wickbom, G.; Landor, J. H.; Bushkin, F. L.; McGuigan, J. E. (Univ. Florida Coll. Medicine, Gainesville 32610). *Gastroenterology* 69(2):448-452, 1975.

Gastric acid output and serum gastrin concentration, both basal and in response to feeding, were compared before and after massive resection of the small intestine. Four mongrel dogs were given Heidenhain pouches and 24 hr secretions were collected from them for a 4-wk period. Acid output was measured by titration. Dogs were fed once daily. Each dog had four feeding tests. After a 36 hr fast, pouch secretions were collected for 60 min and a venous blood sample was taken. Dogs were then fed horsemeat (420 g), and pouch secretions were collected for 6 hr. Blood samples were taken 1, 2, 3, 4 and 6 hr after feeding. The intestine was then resected from 10 in distal to the ligament of Treitz to 10 in proximal to the ileocecal junction. The same daily meal was reinstituted and secretions were collected every 24 hr. Each dog had the four feeding tests repeated. Mean acid output was 9.12 mEq prior to resection and 27.6 mEq after, a 176% increase. At 2 hr after the test meal, gastrin serum concentration (154 pg/ml) was significantly greater after resection than that prior to resection (86 pg/ml). Serum concentrations at 3, 4, 5 and 6 hr after resection significantly exceeded those prior to resection. For 6 hr after feeding there was a high correlation between increases in secretion and in serum gastrin. Integrated serum gastrin response was 2.95 ng/hr/mg prior to resection and 6.74 ng/hr/mg after resection, a 128% increase. It is concluded that gastrin may be responsible for increased acid levels after intestinal resection.

7299 IN VIVO EFFECT OF BILE SALTS AND CHOLESTYRAMINE ON INTESTINAL ANAEROBIC BACTERIA. *(E.)* Williams, R. C.; Showalter, R.; Kern, F., Jr. (Univ Colorado, Sch. Medicine, Denver, Colo. 80220). *Gastroenterology* 69(2):483-491, 1975.

The effect of bile salts on human intestinal anaerobic bacteria *in vivo* was studied. Five normal male subjects (21-26 yr of age) were intubated, serially, into the small bowel before and after administration of bile salts and/or cholestyramine. In two subjects after bile salt administration and in one after cholestyramine, all organisms subcultured were aerobic. Generally, bile salt feeding led to a decline in the number of anaerobic organisms in all five subjects. Ileal anaerobes also decreased after cholestyramine, but the effect was not confined to a certain genome; rather, whichever genome was present was affected. Ileal bile salt concentrations did not correlate with the number of anaerobes. But after cholestyramine administration, there was an increase in the proportion of cholate and decrease in chenodeoxycholate and deoxycholate. The proportion of unconjugated bile salts was low and was unchanged by bile salt or cholestyramine treatment. In *in vitro* studies, only the growth of *Gaffkya anaerobia* was inhibited by cholestyramine. These results are unexplained, but do agree with previous findings.

SMALL INTESTINE

Malabsorption

7351 FAILURE OF LABORATORY AND RADIOLOGICAL STUDIES TO PREDICT JEJUNAL MUCOSAL ATROPHY. *(Eng.)* Sanderson, M. C.; Davis, L. R.; Mowat, A. P. (King's Coll. Hosp., London SE5, England). *Arch. Dis. Child.* 50(7):526-531, 1975.

Fifty-eight infants and children in the early stages of malabsorption were investigated using special metabolic facilities. The data obtained were then compared with the results of small intestinal biopsy in order to assess the value of the preliminary investigations. The cases were allocated to one of two groups according to the small intestine histology: group I, normal histology 31 cases; group II, abnormal histology 27 cases. In group II, 22 patients had subtotal villous atrophy and five had partial villous atrophy. Of the 58 patients, 33 were under three yr of age, 25 above. The final diagnoses of those with a normal histology were: emotional deprivation and/or food refusal (seven), constitutional short stature (four), postgastroenteritis (three), recurrent respiratory infections (three), chronic diarrhea (three), giardiasis (two), habitual vomiting (two), normal child (two), inadequate breast feeding (one), iron deficiency with malabsorption (one), neurofibromatosis (one), dermatitis herpetiformis (one), eczema (one). A rise in blood glucose of less than 40 mg/ml was noted in 15 of 22 patients with abnormal mucosal histology. Rises of less than this were seen in more than 50% of those with normal histology. Fecal fat excretion in excess of 4.5 g/day was noted in 10 of 18 with abnormal histology. A xylose excretion of less than 20% was noted in more than 50% in both groups. Barium lactose examination showed a malabsorption pattern, and in some cases hypolactasis as well, in 13 of 16 with abnormal histology. Of 26 cases with normal histology, seven were abnormal on the barium studies, six of which were regarded as borderline. In patients with villous atrophy, 14 of 20 had a bone age more than 10% below the chronological age, while 13 of 29 with normal histology had a reduced bone age. More than half the patients with villous atrophy had a hemoglobin level of less than 11.5 g as against 25% of those with normal histology. Only two of 27 with normal histology had serum albumin levels of less than 3.5 g/100 ml, while nine of 24 with villous atrophy had low levels. Of 14 with villous atrophy, eight had a rise of triglycerides of less than 50 mg/100 ml; eight of 15 with normal histology had similar low rises. The results of these tests indicate that the application of a number of tests to show malabsorption in children suspected of having celiac disease is unrewarding. No investigation other than small intestine biopsy has shown with certainty the patients with mucosal atrophy and possible gluten enteropathy.

7352 INFLUENCE OF MIXTURES OF TAUROCHOLATE, FATTY ACIDS AND MONOLEIN ON THE TOXIC EFFECTS OF DEOXYCHOLATE IN RAT JEJUNUM IN VIVO. *(E.)* Lamabadusuriya, S. P.; Guiraldes, E.; Harries, J. T. (Inst. Child Health, 30 Guilford, London WC1N 1EH, England). *Gastroenterology* 69(2):463-469, 1975.

The influence of mixtures of taurocholate (TC), fatty acids and monolein (MO) on the inhibitory effects of deoxycholate was studied. In closed-loop studies, deoxycholate (DC) at 2.5 mM induced net secretion of H_2O, Na and Cl into the intestinal lumen. TC (20 mM) plus DC caused a reduction in the movement of H_2O and Na, but not of Cl. A mixture of DC, TC and oleic acid (OA) caused a reduction in DC-induced secretion. Similar effects were noted with mixtures of DC and caprylic acid (CA), and/or MO. These effects were only partial and transport values remained different from controls except for Na. OA (10 mM) emulsions and TC (2.5 mM) had no effect on DC-induced secretion and 20 mM of TC had no effect on H_2O, Na or Cl movements. Inhibition of glucose transport by 5 mM of DC was abolished by a DC, TC and OA mixture. When a mixture of DC, TC and OA was perfused, the inhibition effects of DC were markedly reduced, with net secretion being reversed to net absorption. The reduction in transmural potential difference induced by 1 mM of DC was abolished by mixed micelle solutions. Deoxycholate produced significant inactivation of total and (Na-K)-ATPase and this effect was completely abolished by mixed micellar solution. These results indicate that the mechanism of micelle inactivation in DC action may be a reduced access to jejunal membrane and/or a reduction in the relative concentrations of other bile salts and lipids within the intestinal lumen.

7353 ENTEROPATHY IN ADULT PROTEIN MALNUTRITION: LIGHT MICROSCOPIC FINDINGS.

(E.) Duque, E.; Bolanos, O.; Lotero, H.; Mayoral, L. G. (Universidad del Valle Sch. Medicine, Apartado Aereo 1013, Cali, Colombia, South America). *Am. J. Clin. Nutr.* 28(8):901-913, 1975.

Intestinal morphological findings are presented in conjunction with severe, long-standing primary protein malnutrition. A total of 35 patients were studied (21 males and 14 females, aged 16-69 yr). All patients showed low values in all nutritional and absorptive parameters tested except fecal fat and serum vitamin B_{12}. Most showed slight or moderate abnormalities in intestinal mucosal pattern. Villus height decreased, with widening due to edema and inflammation. Total mucosal thickness was not affected. The mean number of mitoses/five crypts was directly proportional to crypt depth and these ratios were larger in several malnourished patients. A thickening of the epithelial basement and perivascular membranes was observed in 24 of 35 cases. A mononuclear infiltration of the lamina propria was present in all patients. Protein repletion acheived amelioration of both the clinical and histologic abnormalities in all but one patient. The two main findings that characterize the state of severe malnutrition are reduction in intestinal mucosal thickness and atrophy of the crypts. The mild enteropathy of severe protein malnutrition must be considered in the differential diagnosis of malabsorption in the tropical setting. It is concluded that adequate classification of the biopsies and careful histometric evaluation is required.

7354 ENTEROPATHY IN ADULT PROTEIN MALNUTRITION: ULTRASTRUCTURAL FINDINGS.

(E.) Duque, E.; Lotero, H.; Bolanos, O.; Mayoral, L. G. (Universidad del Valle Sch. Medicine, Apartado Aereo 1013, Cali, Colombia, South America). *Am. J. Clin. Nutr.* 28(8):914-924, 1975.

The intestinal ultrastructure of severely malnourished adults with primary (dietetic) protein malnutrition is reported. In all nine patients studied (six males, three females), the biopsies showed varying abnormalities of the absorptive cells. These abnormalities included microvilli slightly shortened, small in number and deviating from the vertical position. No correlation was found between the degree of these abnormalities and the severity of the protein malnutrition or malabsorption. In eight of nine cases, in the subepithelial region a dense, finely granular material was noted, accompanied by collagen fibers immediately below the basement layer. In some areas these deposits and collagen appeared to be united, forming a "complex" between the epithelial and capillary membranes. These findings were believed to be nonspecific, but represented a secondary response to chronic inflammation caused by abnormal intestinal bacterial flora.

7355 ANTI-RETICULIN ANTIBODY IN JEJUNAL JUICE IN CELIAC DISEASE.

(E.) Mawhinney, H.; Love, A. H. G. (Dept. Medicine, Queen's Univ. of Belfast, Belfast BT12 6BN, Northern Ireland). *Clin. Exp. Immunol.* 21(3):394-398, 1975.

Analysis was made of samples of jejunal juice from 14 untreated celiac patients (four men and 10 women, aged 14-69 yr), from 12 patients (five men and seven women, aged 14-59 yr) with normal jejunal biopsies, and from 10 normal control subjects (six men and four women, aged 23-35 yr). The results of the investigation showed that it was possible to demonstrate anti-reticulin antibody in jejunal juice. This antibody was demonstrated only in the immunoglobulin A (IgA) class. IgA anti-reticulin antibody was present in eight of 14 (57%) patients with untreated celiac disease, one of 12 (8%) in the normal biopsy group, and in none of the 10 controls. The presence of anti-reticulin antibody in jejunal juice suggests that this antibody arises as a result of stimulation of the secretory immune system. As the various parts of the secretory immune system function independently, the presence of anti-reticulin antibody in jejunal juice must result from antigenic stimulation of the immunocompetent cells of the small intestine. This supports the theory that reticulin behaves as a dietary protein antigen in celiac disease. Anti-reticulin antibody in the present study differs from antibodies to dietary protein antigens, such as gluten and cow milk proteins, in that antibodies to these proteins have been demonstrated in the jejunal juice not only of celiac patients but also of many subjects with normal jejunal biopsies as well as normal control subjects.

7356 THE IMMUNOGLOBULIN CLASS RESPONSES TO ORAL POLIOVACCINE IN COELIAC DISEASE.

(E.) Mawhinney, H.; Love, A. H. G. (Dept. Medicine, Queen's Univ. of Belfast, Belfast BT12 6BN, Northern Ireland). *Clin. Exp. Immunol.* 21(3):399-406, 1975.

By means of an indirect immunofluoresent technique, the incidence and immunoglobulin (Ig) class distribution of the serum antibody response to type II p. o. polio vaccine was studied in 38 patients (22 women and 16 men, aged 15-72 yr) with adult celiac disease and compared with matched control subjects. Of the 38 patients, 19 (50%) showed an antibody response compared with only seven of 38 control subjects (18%). In 16 of the 38 patients (42%) poliovirus-specific IgA responses were noted, compared with 7 of 38 controls (18%). Poliovirus-specific IgG responses were seen in only 10 of 38 patients (26%) and four of 38 controls (11%). No poliovirus-specific IgM responses were observed. There was no evidence of any difference in the magnitude of the poliovirus-specific IgA or IgG responses in the celiac and control group subjects. The preimmunization poliovirus-specific IgA titers of those who showed an antibody response were significantly higher in the celiac than in the control group. The most striking difference between the patients with celiac disease and the control subjects was the much higher incidence of antibody responses to challenge with p.o. poliovaccine in the group of celiac patients. The explanation for this phenomenon is not known at present.

7357 CHYLOUS ASCITES AND INTESTINAL MUSCULAR HYPERTROPHY OCCURRING IN THE COURSE OF CELIAC SPRUE.

(E.) Kaufmann, H. J. (Katonah Med. Group, N.Y.). *Am. J. Dig. Dis.* 20(5):494-497, 1975.

A 57-yr-old male presented with a 6 yr history of episodic abdominal pain, bloating, and diarrhea, with an associated 10 pound weight loss. Four years earlier an oral cholecystogram showed nonfunction, and a cholecystectomy revealed no abnormalities of the abdominal contents except for an inflammed non-calculous gallbladder. Three years later, exploratory laparotomy showed a milky-white fluid in the abdominal cavity which did not show malignant cells, but did show cholesterol crystals on microscopic examination. The entire small intestine was distended and hypertrophied and showed increased peristaltic activity from the ligament of Treitz to the ileocecal valve. On the present admission X-rays of the gastrointestinal tract with barium showed a dilated but normal colon and a diffusely abnormal small intestine, with dilatation and thickening of the valvulae conniventes. A biopsy of the proximal jejunum with a Crosbly capsule showed a virtually flat mucosa, marked inflammation of the lamina propria, and cuboidal epithelial cells. Treatment with a gluten-free diet brought about improvement in his symptoms. A few months later, tetracycline, 1 g daily, was given due to the presumption that stasis with secondary bacterial overgrowth was present, causing some repeated attacks. Six months later, suspecting an ulcerated area of bowel or a tumor might be causing his bouts of apparent obstruction, a second laparotomy was performed. The proximal half of the small intestine was markedly thickened and dilated. The distal half of the small intestine was almost normal. The colon was dilated. Two large mesenteric nodes were present, the larger of which was microscopically normal. The most striking feature was the great thickening of the muscular layers, which measured 4 mm in the fixed state. The mucosa was consistent with treated celiac sprue. The use of tetracycline was gradually discontinued and the only episodes of pseudoobstruction which now occur seem to follow inadvertent ingestion of gluten. This patient showed the development of chylous ascites in the course of celiac sprue and disappeared on treatment. Its presence was probably related to the mesenteric nodal hyperplasia which is known to occur in celiac sprue.

7358 THE IMMUNE RESPONSE TO ϕX 174 IN MAN. III. EVIDENCE FOR AN ASSOCIATION BETWEEN HYPOSPLENISM AND IMMUNODEFICIENCY IN PATIENTS WITH COELIAC DISEASE.

(E.) Baker, P. G.; Jones, J. V.; Peacock, D. B.; Read, A. E. (Univ. Bristol, Dept. Medicine, Bristol BS10 5NB, England). *Gut* 16(7): 538-542, 1975.

The coliphage ϕX 174 was used to study antibody production in coeliac disease. In all eight cases studied the diagnosis was based on histological changes of subtotal villous atrophy in the jejunal biopsy. Three cases showed a gross impairment of the primary response with a peak antibody level of less than 20. There were no significant changes in the other five cases as to appearance of antibody, rate of titer increase, height and time of peak response or rate of antibody decline. There was considerable impairment in the secondary response. There was a correlation between the severity of the disease and the depression of antibody production. Spleen size was below normal in five of the cases. Serum IgM levels in three cases were abnormally high. It was concluded that patients with coeliac disease have a depressed ability for antibody production with a defect in switching from IgM to IgG antibody.

7359 CHRONIC CELIAC DISEASE COMPLICATED BY A PRIMARY RETICULUM CELL SARCOMA OF THE SMALL INTESTINE.

(Fr.) Rutsaert, J.; Mainguet, P.; Bleiberg, H. (Faculte Medecine Pharmacie, 97, rue aux Laines, Bruxelles, Belgique). *Ann. Anat. Pathol. (Paris)* 19(3):299-310, 1974.

A 33-yr-old patient with celiac disease was the basis of this study. The onset of the illness was in infancy; no specific treatment was recommended during childhood. At 21 yr a gluten-free diet was prescribed. At the age of 31, abdominal pains, diarrhea and x-ray confirmation led to the diagnosis of duodenal stasis which called for exploratory laparotomy. No tumor was found and a duodenojejunostomy was performed. At 32 yr, diarrhea, fever and an inflammatory state were observed. A jejunal biopsy showed severe atrophy of the villi, a month after which an acute abdominal syndrome ensued. Numerous perforated tumors of the jejunum identified as reticulum cell sarcoma and an ileo-cutaneous fistula were discovered. At the age of 33 the patient died in a state of advanced cachexia. A tumoral mass adherent to the spleen, the stomach and the colon was autopsied from the left hypochondrium. A second stomach perforation was discovered, as well as generalized hepatic angiomatosis, and arterial and renal calcifications. Hypotheses were advanced as to the cause of the sarcoma in celiac patients, such as the action of radiation, pre-cancerous state of the atrophic intestinal mucosa, penetration of carcinogenic foods or micro-organisms in an already overstressed mucosa, or possibly an immunologic deficiency. There exists a very probable link between celiac disease and intestinal sarcoma, the pathogenesis of which is still unknown.

7360 ENTEROTOXIGENIC INTESTINAL BACTERIA IN TROPICAL SPRUE. III. PRELIMINARY CHARACTERIZATION OF Klebsiella pneumoniae ENTEROTOXIN.

(E.) Klipstein, F. A.; Engert, R. F. (Univ. Rochester Medical Center, 601 Elmwood Ave., Rochester, N.Y.). *J. Infect. Dis.* 132(2):200-203, 1975.

The enterotoxin secreted by a strain of *Klebsiella pneumoniae* serotype 5, which was the predominant organism cultured from the midjejunal aspirate of a Puerto Rican with tropical sprue, was characterized. Cell-free broth filtrates were prepared by stationary aerobic incubation of cultures in trypticase soy broth. The crude filtrates were freeze-dried, after which portions were heated (100 C for 30 min), treated with acid (pH 4.4), dialyzed through viscose tubing, or subjected to acetone precipitation followed by sequential passage through Diaflo membranes. The various preparations were tested in the ileal loops of 8 to 12-week-old coccidia-free rabbits. The cell-free filtrates retained their capacity to induce fluid secretion in the rabbit ileal loops after heating, acid treatment and dialysis. The acetone precipitate also produced a positive response, which was increased in the ultrafiltration membrane (UM) 2 retentate; the UM 2 filtrate was comparatively less active in this respect, and the UM 10 retentate was inactive. Increasing purification of the *K. pneumoniae* broth filtrate material was associated with a progressive fall in the osmolality of the active fractions. The UM 2 retentate produced a positive fluid response in the ileal loop model when dissolved in isotonic solution. The data indicate that the enterotoxin elaborated by *K. pneumoniae* resembles the previously characterized heat-stable enterotoxin of *E. coli* in a number of respects.

LARGE INTESTINE

7394 WHAT DO WE GAIN FROM THE SIXTH STOOL GUAIAC? *(E.)* Neuhauser, D.; Lewicki, A. M. (Harvard Sch. Publ. Health, Boston, Mass.). *N. Engl. J. Med.* 293(5):226-228, 1975.

The marginal cost involved in implementing the six sequential stool guaiac protocol of Greegor for screening of colonic cancer was analyzed. The expected yield of true-positive results from six se-

ential guaiac tests was calculated for a popula-
on of 10,000 people of whom 72 were assumed to have
lonic cancer. A two guaiac protocol would have a
ue positive rate of 99.31% and a false positive
te of 59.69%. There was little gain in the true
sitive rate from testing beyond the second guaiac
amination, but there was a steadily rising rate in
e false positive group with more frequent testing.
alysis of the expenditures involved in such a pro-
am showed that the cost of detecting cancer rose
ponentially so that the marginal cost of the sixth
st may be 20,000 times the average cost. The mar-
nal cost was decreased with lower test sensitivity
d increased with lower prevalence of colonic can-
r. The results show how an inexpensive test can
come quite expensive if it is to be made available
a larger population group. This high cost is in-
rred with only a small gain in terms of additional
ncer found by the last few guaiac tests of this
ogram. Intuitively, it may then seem more profit-
le to proceed immediately to the barium enema ex-
ination, a completely accurate, if more expensive,
ocedure that needs to be done only once. The mar-
nal cost/case detected depends on the prevalence
the condition in the population screened and the
nsitivity of the test applied.

95 FACTORS AFFECTING THE CONCENTRATION OF COMBUSTIBLE GASES IN THE COLON DURING

LONOSCOPY. *(E.)* Bond, J. H., Jr.; Levitt, M. D.
eterans Admin. Hosp., Minneapolis, Minn. 55417).
stroenterology 68(6):1445-1448, 1975.

e concentrations of H_2 and CH_4 in colonic gas ob-
ined through the colonoscope at the time of colono-
opy were measured in 60 consecutive patients, and
e effects of liquid diet, fasting, and bowel cleans-
g on the rate of production of those colonic gases
re assessed. The colonic concentrations of H_2 and
were well below hazardous levels in all patients
the time of colonoscopy. The mean concentration
H_2 was 0.024% ± 0.007% and of CH_4 was 0.0023% ±
001%. The highest concentration of either gas en-
ntered was only about 1/20 of the minimal explosive
ncentration. These low values could be the result
the colonoscopy preparation procedure and/or dilu-
on with air introduced during colonoscopy. The
ient preparation procedure was analyzed by measur-
g excretion of H_2 and CH_4 in 10 subjects undergoing
tine colonoscopy preparation, in five subjects in-
sting the low residue liquid diet for 48 hr, in 10
unteers who fasted for 12 hr, and in two volun-
ers undergoing the colonic cleansing procedure used
colonoscopy. Hydrogen excretion fell precipi-
sly to about 10% of basal values after 24 hr on
iquid diet and showed a further decline to 5% of
preparation level at the time of colonoscopy.
contrast, CH_4 fell to about 60% of basal levels
day one; however, just prior to colonoscopy, CH_4
retion had declined to only about 15% of the basal
el. In patients on a low-residue liquid diet, H_2
retion rapidly fell to low levels; however, CH_4
retion was minimally reduced. Fasting resulted
a 15-fold reduction in H_2 excretion, but only a
fall in CH_4. Bowel cleansing reduced both H_2
CH_4 10-fold. The results do not support the need for routine CO_2 insufflation prior to colonoscopic electrosurgical polypectomy.

7396 PROBABILISTIC APPLICATION OF PLASMA CARCINOEMBRYONIC ANTIGEN ASSAY IN CANCER PATIENTS.

(E.) Ashman, L. K.; Ludbrook, J.; Marshall, V. R. (Dep. Surg., Univ. Adelaide, Adelaide 5000, South Australia). *Br. Med. J.* 2(5973):721-724, 1975.

In an attempt to establish a more appropriate control group, carcinoembryonic antigen (CEA) levels were determined in patients proved after death to be cancer-free, as the basis against which to compare levels in cancer patients. Plasma samples were assayed for CEA activity in 114 subjects, including 21 healthy volunteers, mean age 24.1 yr, male:female ratio, 1.1:1; 23 patients without cancer, mean age 59.5 yr, male:female ratio, 2.8:1; and 64 cancer patients, mean age 68.4 yr, male:female ratio, 2.2:1. Tumors in this group originated in the lung (22), colon (14), rectum (10), prostate (seven), pancreas (six) and stomach (five). Two radioassay procedures were used: the Roche assay and an assay developed in this laboratory. The mean plasma CEA concentrations in healthy controls by the first technique was 2.42 μg/ml, and by the second, 6.30 μg/ml, and neither group differed significantly from normal. Patient controls had a significantly greater mean CEA level than healthy controls by both procedures. Of 64 cancer patients, 19 by the second assay and 18 by the first assay had plasma CEA levels above the upper 90% confidence limit. When compared with healthy controls, 50 were in this range. Of 19 patients with plasma CEA levels corresponding to a better than 95% probability of cancer, three had disease confined to the organ of origin, four had lymph node involvement and 12 had distant metastases. These data indicate that CEA results should be expressed in probabilistic terms, rather than with the use of a simple cutoff.

7397 COMPARATIVE ELECTRON MICROSCOPIC FEATURES OF NORMAL, HYPERPLASTIC, AND ADENOMATOUS HUMAN COLONIC EPITHELIUM. II. VARIATIONS IN SURFACE ARCHITECTURE FOUND BY SCANNING ELECTRON MICROSCOPY.

(E.) Fenoglio, C. M.; Richart, R. M.; Kaye, G. I. (Coll. Physicians Surgeons, Columbia Univ., New York, N.Y.). *Gastroenterology* 69(1):100-109, 1975.

The architecture and surface cytoplasmic features of the mucosa of normal colon, hyperplastic polyps, and colonic adenomas were studied by scanning electron microscopy. Thirteen hyperplastic polyps and 15 adenomas were taken from patients, along with adjacent normal colonic mucosa. Specimens were fixed in glutaraldehyde and coated with gold-palladium. After scanning, they were reprocessed and stained for light microscopy. Scanning electron microscopy showed the surface architecture of normal colonic mucosa to be arranged in interconnecting territories containing 20-100 crypt mouths each, in parallel linear arrays, separated by deep clefts. Areas were covered by mucinous secretions from the crypt mouths. The hyperplastic polyps were heavily coated with mucinous secretion. In the transition zone to normal mucosa, a similar territorial configuration but in an exagerrated form was seen. Thick cord-like elevations of the surface tapered into a flattened zone which appeared to have lost its normal architecture due to stretching. Nonvillous adenomas had anastomosing cerebriform epithelial cords surrounding deep epithelial depressions that were too wide to be crypt mouths. No normal crypts were identified. When the adenomas were pedunculated, the stalks were normal mucosa. Villous adenomas had more prominent convoluted cerebriform anastomosing ridges separated by deep clefts. In cell arrangement and cytological features, the normal mucosa was coated with an irregular lining of absorptive epithelium with occasional dispersed goblet cells. The lining cells of the crypt appeared to be arranged in overlapping spirals or rings. The tops of the absorptive cells appeared as pentagons covered with closely packed microvilli, while some cells protruded from the surface and had taller, more widely spaced microvilli. There were all gradations between the two types. The microvilli had clubbed tips, possibly an artifact. In the hyperplastic polyps, the polygonal tops of the absorptive cells were stretched into elliptical shapes, especially on the lateral polyp surfaces. Goblet cells were absent at the free surfaces, and absorptive cell microvilli were twice normal size. The polypoid and villous adenomas had nearly total absence of surface goblet cells, but hypersecretory villous adenomas had greater than normal numbers of them. Most adenoma cells were smaller than normal, and departed from the normal polygonal shape. There were occasional large surface cells. Most absorptive cells had short, blunt microvilli, but in some they were elongated fanned tufts. It is concluded that there are divergent patterns of surface morphology in hyperplastic and adenomatous mucosa.

7398 INVESTIGATIVE MEASURES IN DIVERTICULAR DISEASE: RADIOLOGY COLONOSCOPY. *(E.)*

Samuel, E.; Dean, A. C. B. (no affiliation given). *Clin. Gastroenterol.* 4(1):71-84, 1975.

Investigative procedures to demonstrate presence of diverticular disease and to exclude other colonic disease are discussed. In radiological diagnosis, barium enema is the keystone. The diverticula often fail to fill when the barium is administered by mouth. The colon should be cleansed thoroughly, followed by an enema of 1:4 barium sulfate solution after one hr. Injection of air after evacuation is not recommended. The filled diverticulum appears as a flask-shaped projection from the lumen. A spiculated outline of the colon indicates overactivity and thickening of the musculature. Complicating inflammatory change in the diverticular area can only be made with certainty when peri- or paracolic abscess formation or fistulae into another viscus is present. When barium studies have shown some dubiety, such as a narrow irregular segment associated with the diverticula, then colonoscopy is indicated. As with radiology, this should not be carried out until about six weeks after an acute attack of diverticulitis. Regular 10 ml doses of $MgSO_4$ should be given three times daily for 48 hr prior to examination to facilitate cleansing. At sharp bends with narrow lumens, the instrument may be pushed forward, rotating to and fro in a zig-zag fashion, even when out of direct vision. The uninflamed diverticulum appears as an oval porthole lying in normal mucosa, revealing a shadowy cavern beyond. When inflammation is present, it may appear only as a small pit or depression in the swollen mucosa. Differential diagnosis of carcinoma by radiology is difficult when a scirrhous carcinoma distorted by diverticula is present, and must be distinguished from muscular hypertrophy, inflammatory stricture, and pericolic abscesses. With colonoscopy, there is a high failure rate because the instrument may not pass through the narrowed portion. Transintestinal intubation provides a possible solution. Colonoscopy and frozen section biopsy can be performed during laparotomy. Differential diagnosis of Crohn's disease is a less common problem. Symptoms of diarrhea, rectal bleeding and perianal abscess or fistula are suggestive of Crohn's disease. Biopsy and colonoscopy may be helpful. Perforation with peritonitis is the commonest complication of diverticular disease, followed by localized paracolic abscesses and fistulae to the bladder, or the vagina, small bowel, or anterior abdominal wall. Hemorrhage occurs rather uncommonly and usually responds to conservative treatment. Etiology of the disease through radiological and pressure studies is believed to stem from spasm or hypertrophy of the circular muscle, or its crowding by contraction of the longitudinal muscle.

7399 DIVERTICULAR DISEASE OF THE COLON, A 20TH CENTURY PROBLEM. *(E.)*

Painter, N. S.; Burkitt, D. P. (no affiliation given). *Clin. Gastroenterol.* 4(1):3-21, 1975.

The history of colonic diverticular disease, its geographical prevalence, and a hypothesis of its etiology is presented. The disease was not recognized as a clinical problem until about 1900 and surgical cure not practiced until 1942. In the early 1960s the pathology of the disease was linked to high intracolonic pressures. Parenteral morphine injections were found to cause diverticulum-bearing segments of the sigmoid to produce greater pressures (sometimes over 90 mm Hg) than normal segments in the same patient. Cineradiography showed high localized pressures were produced by segmentation of the colon, regardless of the type of stimulus. Prediverticular colons produced higher pressures than normal ones, indicating a primary inward disturbance of motility that resulted in diverticular formation secondarily. A close relationship was found between incidence of the disease and economic development of the geographical area. The disease is almost unknown in Africa, very rare in India and the Middle East, Singapore, Malaysia, Korea, Bangkok, and southern Spain. The diet in these countries contains more fiber than the refined foods of industrialized countries where the disease commonly occurs. The American negro has become increasingly prone to the disease as increasing prosperity has led to his eating less maize, and the high incidence of the disease in Japanese born and bred in Hawaii compared with those living in Japan is accompanied by similar dietary changes. It is hypothesized that a diet containing adequate fiber will pass through the gut in 48 hr (1/2 the time of a refined diet). The gut therefore has less time to absorb water, the fecal stream is not as viscous and the colon need not build up as much pressure as for the viscous low fiber diet. Patients with symptomatic diverticular disease were given a high fiber diet containing miller's bran and reduced sugar. Abdominal pain and distension were relieved in over 85% of the 70 patients. Those who defecated once a week with effort passed soft stools every day. It is concluded that diverticular disease is due to fiber deficiency in the diet.

7400 NATURAL HISTORY OF DIVERTICULAR DISEASE OF THE COLON. *(E.)* Parks, T. G. (no affilation given). *Clin. Gastroenterol.* 4(1):53-69, 1975.

The course and prognosis of symptomatic diverticular disease is reviewed. The incidence increases with age, rising from 5% in the fifth decade to about 50% in the ninth. In one study, 7.7% of patients with the disease were in their ninth decade before presenting with symptoms. Mortality and morbidity are higher in older persons; in one study 20% of all patients in their sixth decade had radiological evidence of diverticulitis compared with 33% of the patients in their ninth. Several surveys found 1.7%, 4.8%, and 2.3% of patients under 40 yr of age. In younger persons it is often aggressive, associated with more troublesome symptoms, and a high complication rate. Studies early in the century showed a preponderance of males (1.6:1 to 3:1) but in the past 30 yr there has been a female preponderance or no differential. Generally, patients with many diverticula were older than those with few. However, the disease does not necessarily progress with age. Many patients also had no increase in diverticular size in 10 yr. There is little evidence that probability of recurrence of diverticulitis and incidence of complications are directly proportional to the number of diverticula. In over 90% of all patients, the sigmoid is the segment affected, and in 45-65%, it is the only segment affected. It has been shown that over 2/3 of the patients are not condemned to relentless advance of the disease; resection is often curative. Patients with extensive or total involvement are no older on the average than those with the disease localized to the sigmoid. Prognosis is related to pathological development in the distal left colon, but not to the more proximal disease. In one study, over 90% of diverticulitis operations involved the sigmoid. Incidence of diverticulitis or peridiverticulitis can be accurately assessed, but has been estimated at 10-20% of patients with diverticula. In one series, 50% of the patients had no symptoms until less than one month prior to referral, and 75% had symptoms less than one yr. Another survey showed 75% of all deaths from the disease occurred in patients who had symptoms less than one month. Of 294 patients, over 50% had symptoms over one yr. Another study showed 45% with symptoms less than one yr and 83% less than five yr. Correlation between symptoms and pathological findings was generally poor. Prognosis was related to symptoms, localized pain giving a better prognosis than generalized pain. Abdominal pain was the commonest symptom in cases requiring hospitalization. Disturbance of bowel habit, nausea and vomiting, distention, and a palpable mass were associated with poorer prognosis. About 40-45% develop recurrent attacks. A high residue diet was effective in treating 80% of 62 patients. In a study of those given resections, 95.6% remained cured (follow-up from 1-16 yr). Proximal colostomy is of limited value in the long term. Closure of colostomy without resection has a high failure rate. Mortality during first hospital stay is about 3%, but may be over 10% when complications are present.

7401 PATHOLOGY OF DIVERTICULAR DISEASE OF THE COLON. *(E.)* Morson, B. C. (no affiliation given). *Clin. Gastroenterol.* 4(1):37-52, 1975.

Diverticular disease occurs in about one of every three people over 60 yr of age in Europe, North America, and Australia. The diverticula consist of a pouch of mucous membrane projecting through the circular muscle layers into the pericolic fat and appendices epiploicae. They include the muscularis mucosae and remain covered by the investing layer of longitudinal muscle. The majority occur at weak points in the circular muscular layer where the main blood vessels penetrate. They are usually confined to the sigmoid, but sometimes spread from there to more proximal locations. The rectum is never involved. Diverticulosis of the right colon only is a separate condition with a high incidence in Hawaii, and may have a different etiology. Isolated diverticula of the right colon are also unrelated to the common forms of the disease, and may be congenital or due to pulsion from high intraluminal pressures. The most consistant feature of diverticular disease of the sigmoid is the muscular abnormality resulting in thick, cartilagenous-like taeniae coli, and corrugated or concertina-like circular muscle. Often the lumen of the bowel is filled with redundant folds of mucous membrane, possibly due to muscular action or pericolic fibrosis. Histologically, the muscle shows thickening, but no hyperplasia or hypertrophy of the muscle cells. Diverticulitis usually begins at the apex of the diverticulum and commonly involves the pericolic and mesenteric fat. Inflammation usually results from abrasion of the mucosa by a fecolith, and rarely occurs in over three or four diverticula in a patient. Pericolic abscesses of diverticulitis are composed of pus and necrotic tissue, are usually chronic in character, and become walled off by fibrous tissue. Crohn's disease may coexist with diverticular disease, and results in an accompanying proctitis or anal lesion. Pathologically, the mucous membrane will be granular or ulcerated, rather than normal as in uncomplicated diverticular disease. Granulomas may be confused with foreign body giant cell reaction to fecal material in pericolic abscesses. Ulcerative colitis, polyps and cancer may also coexist with diverticular disease and should be watched for. Evidence suggests that diverticular disease is due to abnormal increase in the tone of the longitudinal muscle, particularly the taenia coli, which shorten the bowel. Diverticula probably form by pulsion at the weakest point in the wall.

7402 THE TREATMENT AND POSTOPERATIVE COMPLICATIONS OF CONGENITAL MEGACOLON: A 25 YEAR FOLLOWUP. *(Eng.)* Swenson, O.; Sherman, J. O.; Fisher, J. H.; Cohen, E. (Miami Univ. Sch. Medicine, Miami, Fla.). *Ann. Surg.* 182(3):266-273, 1975.

The postoperative complications and long-term follow-up in 483 patients treated by abdominoperineal resection for congenital megacolon are reported. Thirteen pediatric surgeons were contributors to this series. The surgery was performed in a single stage with no preoperative or postoperative ileostomy or colostomy, in two stages with a preoperative ileostomy or colostomy and a takedown of the ostomy at the time of resection, or in three stages, involving a preoperative ostomy, resection, and closure of the ostomy. The patient ages ranged from less than 1 mo to 50 yr, with a mean age of 4.9 yr. There were 16 postoperative deaths (3.3%) and six late deaths (1.2%) from enterocolitis. Immediate postoperative complications included: positive urine cultures in 7.7% of the patients, a wound infection rate of 4.6% (primarily attributable to wound contamination from a preoperative colostomy or ileostomy), dehiscence of the wound in six patients, leak of the coloperineal anastomosis in 24 patients, positive blood cultures in 14 patients, 14 pelvic abscesses, eight intra-abdominal abscesses, and postoperative bowel obstruction requiring laparotomy in 13 cases. Anastomotic leak was unrelated to age at resection or presence of colostomy or ileostomy, but it was significantly increased in patients with Down's syndrome and was most frequent in patients with aganglionosis limited to the rectum. Anastomotic leak significantly increased the incidence of other serious complications. Late postoperative complications included rectal stricture in 30 patients, only seven of whom required a second operation, temporary late soiling in 54 patients, and permanent soiling in 10 patients. Late soiling was significantly more frequent in patients with aganglionosis limited to the rectum than in patients with any other length of aganglionic bowel. There were no patient claims of urinary incontinence or impotence. The low incidence of postoperative complications and the minimal frequency of long-term complications indicate that the abdominoperineal resection is a safe, effective method for the treatment of congenital megacolon.

7403 MELANOSIS COLI: STUDIES OF THE TOXIC EFFECTS OF IRRITANT PURGATIVES. *(E.)*

Steer, H. W.; Colin-Jones, D. G. (Southampton Univ. Medical Sch., England). *J. Pathol.* 115(4):199-206, 1975.

The toxic effects of irritant purgatives were investigated ultrastructurally and histochemically in colonic biopsies from six patients with normal colon and seven patients with melanosis coli. Sections of biopsy tissue were subjected to one of several staining procedures for identification of cytoplasmic organelles. Anthraquinone purgatives increased the number of macrophages in connective tissue of the colonic mucosa. Macrophages near the luminal surface showed more intense acid phosphatase and nonspecific esterase activity than those further away, but no β-glucuronidase activity. Most of the pigment was in the macrophages with less intense acid phosphatase activity; the pigment was positive to Nile blue sulfate method and Schmorl's method indicating the presence of lipofuscin. The purgative also caused an increase in the number of lysosomes in macrophages, Schwann cells, and neurones of the submucosal plexes of the colonic mucosa. An association between lipofuscin and lysosomal particles was confirmed by the finding of acid hydrolases and lipofuscin in macrophages, ganglion cells, and Schwann cells. It is concluded that the effect of anthraquinone cathartics in producing pigmentation is the result of a common cytological response, involving the lysosomes, by different tissues. The pathological effects of these drugs result from their influence on lysosomes in macrophages and nervous tissue.

7404 SURGICAL TREATMENT OF HEREDITARY ADENOMATOSIS OF THE COLON AND RECTUM IN SWEDEN DURING THE LAST 20 YEARS. PART I. INTRODUCTION. SURGICAL PROCEDURES USED. PRE- AND POSTOPERATIVE MEASURES. ARRANGEMENT OF FOLLOW-UP. PROPOSITI GROUP, PRIMARY AND LATE RESULTS. *(E.)*

Alm, T. (St. Erik's Hosp., Stockholm, Sweden). *Acta Chir. Scand.* 141(3):218-227, 1975.

The prevalence of hereditary adenomatosis of the colon and rectum was surveyed in Sweden since 1959. Up to the end of 1972, 97 families were traced and 80 of them were more fully investigated. In 56 of the latter families there were at least two affected members; in the other 24, only one. In all, 340 affected individuals were found, 150 of whom were operated on with the aim of cure. Of these, 82 had presented with symptoms (the propositi group), while 68 affected individuals were detected during the family investigations and underwent prophylactic operations (the call-up group). A comparison was made between the two groups of the primary and long-term results after surgery. Major surgery with total protocolectomy and ileostomy or colectomy with ileorectal anastomosis was performed in 67 propositi and 68 call-up patients; minor surgery with segmental resection was performed in 15 propositi. In the propositi group there were three surgical deaths. At the time of operation 48 patients had already developed cancer. Up to the end of the observation period, 16 had died from metastases, two of other malignancies, and three of nonmalignant disease. In the call-up group, there were three surgical deaths and two late deaths from metastases and other malignancy.

7405 SURGICAL TREATMENT OF HEREDITARY ADENOMATOSIS OF THE COLON AND RECTUM IN SWEDEN DURING THE LAST 20 YEARS. PART II. PATIENTS WITH PROPHYLACTIC OPERATIONS, PRIMARY AND LATE RESULTS. DISCUSSION AND SUMMARY. *(E.)*

Alm, T. (St. Erik's Hosp., Stockholm, Sweden). *Acta Chir. Scand.* 141(3):228-237, 1975.

The surgical treatment of patients with hereditary adenomatosis of the colon and rectum is described as part of an investigation, started in 1959, of Swedish families. There were 68 affected, but symptom-free, individuals detected and referred for surgical treatment. Total proctocolectomy and ileostomy were performed in ten cases, colectomy with ileorectal anastomosis in 58. The surgical mortality was 4.4%. Six patients had cancer at the time of operation, and two other patients were operated on for colonic cancer many years prior to the diagnosis of adenomatosis of the colon and rectum. One of those eight patients died from metastases. Primary malignant kidney tumor was responsible for the only additional late death in this group. In another group of patients operated on because of symptoms, cancer was found in 48 patients, 16 of whom died from metastases. Families in which the disease runs should be placed under continuous supervision. To make this practicable on a large scale, a well functioning central register is necessary. Children of an affected parent should be called for examination at regular intervals over an indefinite period, or at least up to the age of 40. Whenever the disease is diagnosed, the patient should be referred to surgery as soon as is convenient. In the vast majority of cases ileorectal anastomosis is the operative procedure of choice.

7406 IMMUNOTHERAPY OF EXPERIMENTAL COLON CANCER: IMMUNOLOGIC ENHANCEMENT OF GRAFTED TUMOR.

(Fr.) Martin, M. S.; Martin, F.; Lagneau, A.; Horiot, J. C.; Chomono, R. (Laboratoire de Medecine Experimentale et d'Immunologie, et centre G. F. Leclerc, Faculte de Medecine, boulevard Jeanne d'Arc, F 21033 Dijon, France). *Biol. Gastroenterol. (Paris)* 7(4): 249-252, 1974.

Two techniques of immunization were used in this study of 42 BD-IX strain rats (21 test animals and 21 controls). Immunization was induced by six s.c. grafts of a DHB line syngeneic colon carcinoma sterilized by irradiation. The control animals underwent a "test" operation to standardize surgical procedures. Immunization was continued by two injections of 10^6 live cells obtained from trypsinization of DHB treated by mitomycin and neuraminidase. Mitomycin is a radiomimetic agent which blocks cellular multiplication and neuraminidase probably unveils immunological sites masked by sialic acid. Three weeks after the last "immunizing" injection, all the remaining animals (18 immunized, 17 controls) were injected s.c. with 10^6 viable untreated cells. The tumor grew in all immunized animals and in ten of 17 control animals, the tumor weighing 3,104 mg and 412 mg, resp. The results indicate reverse immunoprotection of unknown mechanism which leads to enhancement of the tumor. It has been suggested that the cause may be a preponderance of the tumor response (antibody) over the cellular one (lymphocytes). The results call attention to the potential hazards of immunotherapy in human colonic cancer.

7407 SIMULTANEOUS OCCURRENCE OF MULTIPLE GASTRIC CARCINOMAS AND FAMILIAL POLYPOSIS OF THE COLON.

(E.) Ohsato, K.; Watanabe, H.; Itoh, H.; Yao, T.; Nishimura, M. (Kyushu Univ. Faculty Medicine, Fukuoka 812, Japan). *Jpn. J. Surg.* 4(3): 165-174, 1975.

The simultaneous occurrence of multiple gastric carcinomas and familial polyposis of the colon is reported in ten cases. Heredity was confirmed in nine of the ten cases. In eight of the ten cases subjected to detailed study of the upper gastrointestinal tract, polyps and/or carcinomas were detected in the stomach and/or duodenum. Gastric and/or duodenal polyps were found in seven, including one case with concomitant presence of multiple gastric carcinomas. In one case, only carcinomas in the stomach were detected. Histological studies on these polyps revealed all were adenomas except for one case of hamartomatous polyposis. Polyps were not found in small intestine on x-ray examination. All cases except one were treated surgically with single or multiple stage procedures. Total colectomy with or without resection of the rectum was followed by ileorectal anastomosis in six and permanent ileostomy in three. New polyps arising in the preserved rectum after ileoproctostomy were fulgurated or extirpated. There was no surgical death. The presence of numerous adenomas was confirmed in resected and autopsy specimens of the colon and rectum. Adenocarcinomas were present in nine of the ten cases. The rather frequent association of gastroduodenal polyps and cancerous lesions in familial polyposis suggests that such association is a part of the manifestation of this inherited disease. The association indicates that the potential for malignancy occurs not only in the large intestine but in the gastroduodenal mucosa.

7408 CANCER OF THE COLON: SOCIOECONOMIC VARIABLES IN A COMMUNITY.

(E.) Lynch, H. T.; Guirgis, H.; Lynch, J.; Brodkey, F. D.; Magee, H. (Creighton Univ. Sch. Medicine, Omaha, Nebr. 68178). *Am. J. Epidemiol.* 102(2):119-127, 1975.

The relation between socioeconomic factors and the incidence of cancer of the colon was studied in Omaha-Douglas County, Nebraska, (population 345,000) in 1964. Sources of data were medical records from all of the community hospitals and pathology departments, physicians' records and patient interviews. A total of 154 cases of colon cancer were identified in the county in question in 1964 (incidence rate of 44.7/100,000 of population). The median age of the colon cancer probands was 67.2 yr and no significant sex differences were identified. No specific association was observed with any specific occupation and the reported smoking habits did not vary significantly from expectations in this population. Of the 154 cases, 9.7% had one or more first degree relatives with colon cancer and 45.8% had one or more first degree relatives with a history of cancer of any anatomic site. There was a greater frequency of colon cancer in patients living in census tracts with higher average income than in those with lower average income. The opposite was true of esophageal cancer; no familial occurrences of this disease were observed. There was a slight preponderance of affected blacks. Although the survival rate with colon cancer was consistently lower in the lowest socioeconomic group than in the highest socioeconomic group, the difference was minimal. Cancer control implications suggest that screening for colon cancer should be most rigorous among the highest socioeconomic groups.

7409 CARCINOMA OF THE RIGHT COLON.

(E.) Sawhney, K. K.; Kambouris, A. A. (V. A. Hosp., Detroit, Mich.). *Am. Surg.* 41(6):364-369, 1975.

Records of 93 patients with carcinoma of the cecum, appendix, ascending colon, and hepatic flexure were reviewed with respect to primary characteristics and treatment results. The patients ranged in age from 27 to 92; 62.4% were female and 37.6% male. The most frequent symptoms were abdominal pain, weight loss, and weakness. Nausea and vomiting, blood in the stool, and diarrhea were also common. A mass in the right lower quadrant was present in 46%. Intestinal obstruction was present in 12, 75% of which had the tumor in the cecum. Barium enema was performed in 90% and was diagnostic in all but one case. In 50% of the patients, hemoglobin was under 10 g% and in 80% it was under 12.5 g%. Occult blood was in the stools of 50% of 40 patients tested. In 15 cases the tumor was grossly limited within the colonic coats, in 26 it extended to the pericolic fat, in 29 there were metastases to the regional lymph nodes, and in 18 there were metastases to other intraabdominal organs, notably the liver. A right hemicolectomy was performed in 81 (87%). In three the tumor was not resectable and an ileotransverse colostomy was performed. Of four patients with carcinoma of the appendix, three had appendectomy only, and one a delayed right colectomy. In five inoperable patients, chemotherapy was given in four and radiotherapy in one. There were altogether 49 lesions in the cecum, four in the appendix, 41 in the ascending colon, and four in the hepatic flexure. Five patients had multiple lesions, 22 had associated adenomatous polyps, and five had previous intestinal carcinoma. Of the 88 patients given surgery, 13 (14.7%) died within one month: four from peritoneal sepsis, seven from cardiopulmonary causes, one from hypoglycemic shock, and one from cerebral thrombosis. Eighteen patients developed postoperative ileus, 13 wound infections, 4 wound dehiscence, 6 fecal fistulas, and 12 postoperative obstruction. Twelve developed cardiorespiratory complications. Of the 81 right hemicolectomies performed, 64 (79%) were curative, and 17 (21%) palliative. Of the 88 patients operated upon, 40 died during a 5-10 yr follow-up. Of 27 who died during this period, 50% died within 12 months. Overall mortality was 14.7%. Absolute 5-yr survival was 32.2% among all 93 patients. No conclusions are drawn.

7410 ACUTE COMPLICATIONS OF COLO-RECTAL CANCER: SITE, STAGE AND SURVIVAL.

(E.) Fielding, L. P.; Wells, B. W.; Payne, P. M. (St. Mary's Hosp., London, W.2 England). *Clin. Oncol.* 1(2):121-126, 1975.

A series of patients with colorectal cancer was examined to determine whether this disease has a favorable prognosis, and whether patients who present for admission with an emergency differ in terms of age, tumor site, and degree of spread of tumor from those who present for elective treatment. Of 388 patients studied, 155 presented with an emergency. Large intestinal obstruction was the presenting feature in 90; peritonitis was present in 28; diarrhea, abdominal pain and rectal bleeding were seen in 16; and the remaining 21 presented with other emergencies. Only two of 59 patients who did not undergo surgery survived more than 1 yr, and all died by 2 yr. Laparotomy with or without a drainage procedure was carried out in 82 patients: 19 survived 1 yr and seven survived 2 yr. If distant metastases were present at the time of surgery (99 cases) the chances of survival for 1 yr were one in three, and only three patients survived longer than 3 yr. Patients who were emergency admissions and had their tumors resected had a significantly shorted survival time after 3 yr than those receiving elective resection ($P < 0.02$). There was no difference between the groups in the incidence of lymph node or hepatic involvement. The proportion of Dukes' B tumors in the emergency group was greater than that in the elective group (39 and 29%, resp.). The difference in resection rates between the groups was large: 44 and 72% for the emergency and elective groups, resp. The poorer survival figures in the emergency group may partly result from the greater extent of spread of the primary tumor or possibly from the delay associated with a staged resection.

7411 EPIDERMOID CYSTS, POLYPOSIS COLI AND GARDNER'S SYNDROME.

(E.) Leppard, B.; Bussey, H. J. R. (St. John's Hosp. for Diseases of the Skin, London, WC2H, 7BJ, England). *Br. J. Surg.* 62(5):387-393, 1975.

The nature, incidence, and mode of inheritance of the skin cysts of Gardner's syndrome were investigated in 196 members of 15 families with Gardner's syndrome as part of a large survey of benign familial skin tumors. Sixty patients were interviewed either at the hospital or at home. Information from hospital notes was available on 82 patients, 25 replied to letters, and information on 29 was obtained from other members of their families. Cysts of the skin were found in 39 of the 74 patients with polyposis. Microscopical examination of 24 cysts from 15 patients all showed the characteristic features of epidermoid cysts. No examples of pilar cysts or steatocystoma multiplex were found. The number of cysts/patient varied from one to 20, the average was four. In only one patient were they large and disfiguring. The age of onset of the cysts was from birth to 35 yr, with an average of 13 yr. Based on four pedigrees studied, it is concluded that polyposis coli is inherited as an autosomal dominant trait. At present it is not possible to say if Gardner's syndrome is the same as, or different from, familial polyposis. Until all patients with colonic polyps have a full clinical examination for surface tumors, x-rays of the skull and long bones to detect osteomas, and dental x-rays for abnormalities of the teeth, this question will remain unanswered.

7412 EFFECTS OF TWO TYPES OF DIETARY FIBRE IN FAECAL STEROID AND LIPID EXCRETION.

(E.) Walters, R. L.; Baird, I. M.; Davies, P. S.; Hill, M. J.; Southgate, D. A. T.; Green, J.; Morgan, B. (West Middlesex Hosp., Isleworth, Middlesex, England). *Br. Med. J.* 2(5970):536-538, 1975.

The effects of sugar cane residue and wheat bran on stool weight and fecal excretion of acid, neutral steroids and lipids were studied, as well as the effects of sugar cane residue on plasma cholesterol and triglyceride levels, gastrointestinal transit and fecal bacterial flora. Of 19 healthy women in the sugar cane residue group, nine were given a supplement of 10.5 g of the residue in biscuit form and the other ten were given control biscuits low in fiber. Another five subjects were given a supplement of 39 g of wheat bran. The addition of sugar cane residue increased the total dietary fiber by almost 9 g/day in the first group. Stool dry weight in this group was increased by 50% and wet weight by almost 60%. There was an increased daily loss of acid steroids and fatty acids. Elevated excretion of bile and fatty acids did not cause any lowering of plasma cholesterol or triglyceride levels. Gastrointestinal transit time was significantly reduced and there were physicochemical changes in the feces, but the composition of the fecal flora did not change. The average control level of dietary fiber (14 g) was increased to 27 g by the bran supplement. Dilutional effects were observed for both acid and neutral steroids. It is suggested that the different effects of sugar cane residue and wheat bran on steroid excretion are due to differences in their chemical composition.

7413 COLONIC ELECTROLYTE TRANSPORT IN HEALTH AND IN CONGENITAL CHLORIDE DIARRHEA.

(E.) Holmberg, C.; Perheentupa, J.; Launiala, K. (Children's Hosp., Univ. Helsinki, Helsinki, Finland, SF 00290). *J. Clin. Invest.* 56(2):302-310, 1975.

The colonic defect in congenital chloride diarrhea was studied, in addition to normal transport, in three patients with the defect and in their three healthy siblings. Colonic perfusions with $^{36}Cl^-$ were performed. In eight perfusions of the controls, the mean flow of the ileal effluent was 0.9 ml/min and the mean concentrations were: Na^+, 108.3; K^+, 8.8; Cl^-, 67.9; and HCO_3^-, 25.3 mEq/l. In 12 perfusions of the patients, the mean rate was 1.8 ml/min and the mean concentrations were: Na^+, 100.0 mEq/l; K^+, 7.3 mEq/l; Cl^-, 118.0 mEq/l; HCO_3^+, 3.4 mEq/l. There was a marked reduction of Cl^- transport in patients compared to controls. With an extracellular fluid-like perfusate, there was almost no movement of Cl^-. Both influx and efflux were minimal. Reduction of Cl^- concentration in the perfusate caused net secretion of Cl^-. In contrast to controls, absence of HCO_3^- did not alter the Cl^- movement. Absorption of Na^+ was impaired when the luminal contents were acid; net K^+ secretion was increased. These data suggest a defect in the carrier-mediated Cl^-/HCO_3^- exchange mechanism as responsible for the transport impairment in congenital chloride diarrhea.

7414 DISODIUM CROMOGLYCATE IN THE TREATMENT OF CHRONIC PROCTITIS.

(E.) Heatley, R. V.; Calcraft, B. J.; Rhodes, J.; Owen, E.; Evans, B. K. (Univ. Hosp. Wales, Cardiff, Wales). *Gut* 16(7): 559-563, 1975.

A randomized, double-blind, crossover trial was conducted to examine the effect of disodium cromoglycate (DSCG) on chronic proctitis. Twenty-six patients (mean age of 39 years) with chronic proctitis were studied. All active symptoms were present, including: rectal bleeding, mucus passage, decreased frequency of bowel movement and abnormal rectal mucosa on sigmoidoscopy. One hundred mg of DSCG was given p.o. three times/day and 200 mg was self-administered by enema for a period of 4 wk. The three measures of clinical response were: change in sigmoidoscopy, change in bowel frequency and change in blood loss. There was no significant change in the hemoglobin, WBC, ESR or serum IgE levels during the treatment. Patients who responded to DSCG (14 of 26) had significantly more eosinophils in their rectal biopsies than nonrespondents. There was poor correlation between the mucosal inflammatory reaction and changes in the clinical response and sigmoidoscopic appearance. This study provides evidence suggesting that immune mechanisms are important in the pathogenesis of some cases of proctitis and DSCG may play a role in routine patient management.

7415 THE RESPONSE OF THE DOG COLON MUCOSA ONE HOUR'S ISCHAEMIA.

(E.) Robinson, J. W. L.; Menge, H.; Mirkovitch, V. (Hopital Cantonal Universitaire, CH-1011 Lausanne, Suisse). *Res. Exp. Med. (Berl.)* 165(2):127-134, 1975.

The morphology and function of segments of dog colon were studied immediately after or 24 hr after brief ischemia (one hr). Functional analysis of the mucosa consisted of both transport and metabolic studies and included the determination of net sodium transport across the mucosa *in vitro*, the transport capacity *in vitro* for sugars and amino acids, tissue respiration, lactate production and the liberation of acid phosphatase. Immediately after the ischemia, all parameters differed significantly from the control mucosa: net sodium transport was abolished; amino acid and sugar uptake, oxygen consumption and lactate production were reduced; and lysosomal enzyme release was increased. All parameters, except sugar uptake, had normalized 24 hr after the trauma. Histological examinations revealed such variation in the lesions occurring after the ischemia, varying from slight epithelial desquamation to considerable mucosal destruction. In most cases, the mucosa had almost normalized 24 hr later. Morphometric analysis revealed decreased mean mucosal thickness immediately after the trauma, though 24 hr later there was again no significant difference with the control group. The results demonstrate that the colon, like the small intestine, loses most of its functional properties immediately after brief ischemia, but it is able to recover most of its functional integrity within 24 hr of the insult. The extent of the morphological damage of the colon immediately after the ischemia is much more discrete than that occurring in the ileum. This finding indicates that, despite the apparent identity of the functional results, both the sensitivity of the colon to ischemia and its regenerative capacity are less extreme than those of the small intestine.

7416 BACTERIAL STUDIES OF CLINDAMYCIN-ASSOCIATED COLITIS: A PRELIMINARY REPORT.

(E.) Marr, J. J.; Sans, M. D.; Tedesco, F. J. (Washington Univ. Sch. Medicine, St. Louis, Mo. 63110). *Gastroenterology* 69(2):352-358, 1975.

The proctoscopical and bacteriological features of clindamycin-associated colitis were correlated. All patients (16) were taking clindamycin; none were on any other antibiotic. All patients developed diarrhea and underwent proctoscopy; during the procedure fecal specimens were taken and cultured. Biopsies were also taken. In five patients with diarrhea, but not pseudomembranous colitis, fecal cultures showed a variety of anaerobic organisms approximating that in normal intestinal flora. In six patients with pseudomembranous colitis, there was a striking decrease or absence of anaerobic organisms (one anaerobe in three patients and in the other three, no anaerobes). Most had facultative flora, including *Escherichia coli*, *Klebsiella-enterobacter* sp., *Proteus* sp. and enterococci. Five patients with resolving colitis (2-3 weeks after biopsy-proven pseudomembranous colitis had subsided) showed normal numbers of anaerobes. There seemed to be fewer species, but this was not conclusive. All three groups appeared to have the same population of facultative organisms. It is concluded that the disappearance of pseudomembranous colitis is associated with regrowth of anaerobic flora.

7417 CYTOMEGALIC VIRUS INFECTION OF BOWEL IN ADULTS. *(E.)* Dent, D. M.; Duys, P. J.; Bird, A. R.; Birkenstock, W. E. (Groote Schuur Hosp., Capetown, South Africa). *S. Afr. Med. J.* 49(16):669-672, 1975.

Two cases of cytomegalic inclusion virus (CMV) infection of the bowel are presented. A white female with a history of Crohn's disease presented with severe attacks of pain and diarrhea. Barium studies disclosed multiple colox-colic fistulae, which responded to conservative therapy. After six yr she presented with pyrexia, dysentery, weight loss, and painful ulcers of the tongue, mouth, and conjunctivae. A variety of antibiotics, azathioprine (100 mg/day for 2 weeks), and prednisone (80 mg/day for 11 days) failed to help. Laparotomy revealed the entire colon to be thickened with dense adhesions between loops of colon and adjacent ileum. The ileum also appeared abnormal and inflamed. Postoperatively, the patient developed bilateral bronchopneumonia and died. Histologically, the colon showed extensive ulceration with an inflammatory cell infiltrate of lymphocytes, histiocytes, and plasma cells. Throughout the involved areas of the colon were enlarged cells containing eosinophilic intranuclear inclusions surrounded by halos, and extensive bacterial bronchopneumonia. The second case was a black male who presented with watery, offensive stools, vomiting and loss of appetite, weight loss, swelling of the legs and abdomen, and abdominal pain with audible borborygmi. Laparotomy revealed ascites, and the entire length of the bowel was edematous. The terminal 50 cm of the ileum was grossly thickened. This portion was resected, but the patient died postoperatively of bilateral bronchopneumonia. The resected section of ileum showed a cobblestone appearance with pseudopolypi and minute areas of ulceration. The mucosa had heavy infiltration of histiocytes. Large cells with intranuclear inclusions were present in relation to the ulcerated areas and to the capillaries. The first case appears to be Crohn's disease in which CMV was an opportunistic invader. The second case showed a histology unlike tuberculosis, lymphoma, or Crohn's disease, and may represent primary bowel disease caused by CMV. It is concluded that clinicians should be aware of the possibility of CMV disease in patients debilitated by illness and cytotoxic therapy; that preexisting pathology may be modified by CMV invasion; and that diagnosis must be made by culture, or colonic or rectal biopsy.

7453 HEMORRHAGE OF THE LARGE INTESTINE. *(It.)* Marinoni, P. L.; Fichera, G.; Mirelli, E. (Surgery Clinic I, Univ. Milan, Milan, Italy). *Minerva Gastroenterol.* 20(2):62-63, 1974.

7454 LARGE INTESTINAL ENDOMETRIOSIS SIMULATING RECURRENT APPENDICITIS. A CASE REPORT CONCERNING DIFFERENTIAL DIAGNOSIS. *(Ger.)* Mainhof, U.; Diamantopoulos, G. (Municipal Hosp. Inst., Ludwigshafen, Germany). *Chirurg* 46(2):92-94, 1975.

7455 MANOMETRIC EXPLORATION OF THE ANO-RECTAL CANAL IN INFANTS: APPLICATION TO MEGACOLON. *(Fr.)* Meunier, P.; Mollard, P.; Jaubert de Beaujeu, M. (Debrousse Hosp., Lyon, France). *Pediatrie* 29(7):679-688, 1974.

7456 RADIOLOGICAL EVALUATION OF DISEASES OF THE COLON USING MAGNIFICATION TECHNIQUE ON RESECTED SPECIMENS OF COLON. *(Jpn.)* Inakura, M.; Koga, M.; Kiyonari, H.; Tanaka, M.; Koga, N.; Furusawa, M.; Nobe, H.; Nakata, S.; Ohsato, K.; Soegima, K.; Sannohe, Y.; Umayahara, A.; Matsuura, R.; Haraguchi, Y.; Shizaki, T.; Takeshita, T. (Kyushu Cancer Center, Kyushu, Japan). *Rinsho Hoshansen* 19(12):925-931, 1974.

7457 ASSOCIATION OF RECTAL-COLONIC HEMORRHAGE AND HEMOLYTIC ANEMIA WITH AUTO-ANTIBODIES. *(Fr.)* Streiff, F.; Mauuary, G.; Raffoux, C.; Bordigoni, P.; Zuck, P.; Duc, M.; Gabriele, R. (Centre de Transfusion Sanguine, France). *Ann. Med. Nancy* 14:175-176, 179-180, 1975.

7458 CHRONIC INTUSSUSCEPTION OF THE COLON CAUSED BY ADHESIONS. *(Sp.)* Bocanegra Carranza, A.; Castillo Bernabeau, R. (Hospital Nino Jesus, Madrid, Spain). *Pediatr. Esp.* 33(387):111-114, 1975.

7459 FALSE-POSITIVE FINDINGS OF TUMORS IN THE CECUM. *(Ger.)* Taenzer, V.; Albrecht, A.; Anders, A. (714 Ludwigsburg, Krankenanstalten, Germany). *Fortschr. Geb. Roentgenstr. Nuklearmed.* 122(5):385-390, 1975.

7460 TOXIC MEGACOLON: HISTOPATHOLOGICAL STUDY AND CONSIDERATION OF ITS ETIOLOGY AND PATHOGENESIS. *(It.)* Boscaino, N.; Gambardella, P.; Romano, C. (Ospedale Ascalesi, Naples, Italy). *Arch. Ital. Chir.* 98(4):405-416, 1974.

7461 RADIOLOGICAL CONTRIBUTION TO RECTAL MANIFESTATIONS OF MYELOFIBROSIS. *(Ger.)* Hartweg, H.; Schwegler, N. (Kantonsspital Basel, CH-4004 Basel, Switzerland). *Fortschr. Geb. Roentgenstr. Nuklearmed.* 122(5):445-448, 1975.

7462 PNEUMATOSIS CYSTOIDES INTESTINALIS: REVIEW OF THE CLINICAL SYMPTOMS ON THE BASIS OF ONE CASE REPORT. *(Ger.)* Muller-Farber, J.; Eppinger, G. (Stadt, Krankenhaus, Stuttgart-Bad Cannstatt, Germany). *Med. Welt.* 26(20):995-998, 1975.

7463 TUBULAR DUPLICATION OF THE DESCENDING COLON, SIGMOID, AND RECTUM. *(Ger.)* Daum, R. (Chirurgische Universitatsklinik, 69 Heidelberg, Kirschnerstrasse 1, Germany). *Z. Kinderchir. Grenzgeb.* 15(4):469-471, 1974.

7464 POLYPS OF THE COLON. *(Nor.)* Osnes, M.; Myren, J.; Serck-Hanssen, A. (Ulleval sykehus, Oslo, Norway). *Tidsskr. Nor. Laegeforen.* 95(6):365-369, 1975.

7465 PEUTZ-JEGHER SYNDROME. *(Rus.)* Tronnikov, A. T. (Khanzhenkovo Medical Sanitation Hosp., Makeevka, Donetsk District, USSR). *Vestn. Khir.* (5):142-143, 1975.

7466 EMERGENCY SURGERY FOR COMPLICATED FORMS OF CANCER OF THE COLON. *(Rus.)* Rozanov, I. B.; Matveev, V. I.; Shalimov, V. A. (S. P. Botkin Hosp., Moscow, USSR). *Klin. Khir.* (6):63-65, 1975.

7467 VILLOUS TUMORS WITH WATER AND ELECTROLYTE IMBALANCES: 2 CASES. *(Fr.)* Lanson, Y.; Metman, E. H.; Jankowski, J. M.; Benatre, A. (Faculte Medecine Tours, France). *Rev. Fr. Gastroenterol.* (108):25-28, 31, 1975.

7468 DEFECTS IN THE ABDOMINAL AND PERINEAL MUSCULATURE IN DIVERTICULOSIS OF THE COLON: 820 CASES. *(Fr.)* Bertrand, J. (No affiliation given). *Rev. Fr. Gastroenterol.* (108):7-10, 13, 1975.

7469 A CASE OF COLONIC STENOSIS, FOLLOWING NECROTIZING ENTEROCOLITIS. *(Ger.)* Meradji, M. (Inst. Radiol., Erasmus Univ., Rotterdam, Netherlands). *Z. Kinderchir. Grenzgeb.* 16(3):310-312, 1975.

7470 LATE DIAGNOSIS OF CARCINOMAS OF THE SIGMOID AND RECTUM. *(Ger.)* Kieninger, G.; Berger, P. (Chirurgische Klinik und Poliklinik, Universitat Tubingen, Tubingen, Germany). *Zentralbl. Chir.* 100(6):352-358, 1975.

7471 CLINICAL AND ICONOGRAPHIC STUDY OF THE COLIC FORMS OF CROHN'S DISEASE. REPORT OF 40 PERSONAL CASES. *(Fr.)* Yvergneaux, J. P.; Bauwens, E.; De Puydt, W.; Biot, M.; Yvergneaux, E. (Algemene Kliniek H, Familie, Gent, Belgium). *Acta Gastroenterol. Belg.* 38(1/2):49-76, 1975.

7472 COMPLICATIONS OF DIVERTICULAR DISEASE: INFLAMMATION, OBSTRUCTION AND BLEEDING. *(E.)* Hughes, L. E. (No affiliation given). *Clin. Gastroenterol.* 4(1):147-170, 1975.

7473 MEDICAL AND DIETARY MANAGEMENT. *(E.)* Eastwood, M. A. (No affiliation given). *Clin. Gastroenterol.* 4(1):85-97, 1975.

7474 FISTULA AND CONDITIONS ASSOCIATED WITH DIVERTICULAR DISEASE OF THE COLON. *(E.)* Small, W. P.; Smith, A. N. (No affiliation given). *Clin. Gastroenterol.* 4(1):171-199, 1975.

7475 APPLIED PHYSIOLOGY OF THE COLON: FACTORS RELEVANT TO DIVERTICULAR DISEASE. *(E.)* Connell, A. M. (No affiliation given). *Clin. Gastroenterol.* 4(1):23-36, 1975.

7476 CLINDAMYCIN-ASSOCIATED COLITIS. *(E.)* Totten, M. A.; Kaminsky, D. B. (New England Deaconess Hosp., 185 Pilgrim Road, Boston, Mass. 02115). *Am. J. Gastroenterol.* 63(5):404-407, 1975.

7477 PSEUDOMEMBRANOUS COLITIS ASSOCIATED WITH CLINDAMYCIN THERAPY. *(E.)* Jacobson, J. R. (No affiliation given). *Rocky Mt. Med. J.* 72(5):193-195, 1975.

7478 STATISTICAL ANALYSIS OF DIVERTICULOSIS OF THE COLON. *(E.)* Nakasaka, T.; Watanabe, H.; Yamagata, S.; Munakata, A.; Tajima, T.; Matsunaga, F. (Tohoku Univ. Sch. Medicine, Tokyo, Japan). *Tohoku J. Exp. Med.* 115(3):271-275, 1975.

7479 MULTIPLE FILLING DEFECTS IN THE COLON. *(E.)* Madewell, J. E.; Reeder, M. M. (Armed Forces Inst. Pathology, Washington, D.C.). *JAMA* 232(2):172-173, 1975.

7480 EMERGENCY COLOSCOPY IN THE MANAGEMENT OF THE ACUTE PERANAL HEMORRHAGE. *(E.)* Deyhle, P.; Blum, A. L.; Nuesch, H. J.; Jenny, S. (Dept. fur Innere Medizin der Univ. Zurich, Med. Klinik, Stadtspital Triemli, Zurich, Germany). *Endoscopy* 6(4):229-232, 1974.

7481 EVALUATION OF THE COLONOSCOPIC EXAMINATION: RESULTS OF THREE STUDIES. *(E.)* Williams, C. (St. Mark's Hosp., City Road, London, ECIV 2PS, England). *Dis. Colon Rectum* 18(5):366-368, 1975.

7482 EVALUATION OF THE COLONOSCOPIC EXAMINATION: COMPLICATIONS. *(E.)* Gathright Jr., J. B. (No affiliation given). *Dis. Colon Rectum* 18(5):374-375, 1975.

7483 BASAL-CELL CARCINOMA ORIGINATING AT THE COLOSTOMY SITE: REPORT OF A CASE. *(E.)* Didolkar, M. S.; Douglass, H. O.; Holyoke, E. D.; Elias, E. G. (Roswell Park Memorial Institute, New York State Dept. Health, 666 Elm St., Buffalo, N.Y. 14263). *Dis. Colon Rectum* 18(5):399-402, 1975.

7484 EXTRAPERITONEAL PERFORATION OF THE RECTUM DURING BARIUM ENEMA. *(E.)* Rosenklint, A.; Buemann, B.; Hansen, P.; Baden, H. (Dept. Surgical Gastroenterology (Division S), Gentofte Hosp., DK-2900 Hellerup, Denmark). *Gut* 15(11):87-90, 1975.
